Abstract. A quasistatic rate-independent adhesive delamination problem of laminated plates with a finite thickness is considered. By letting the thickness of the plates go to zero, a rate-independent delamination model for a laminated Kirchhoff-Love plate is obtained as limit of these quasistatic processes. The same dimension reduction procedure is eventually applied to processes which are sensitive to delamination modes, namely opening vs. shearing is distinguished.

Key Words. Adhesive contact, delamination, mixed modes, rate-independent processes, dimension reduction, Γ-convergence, Kirchhoff-Love plates.

1 Introduction, notation, basic concepts

This paper aims to study delamination of sandwich-like laminated plates. In particular, a two-dimensional model for the quasistatic evolution of the delamination process is rigorously derived by dimension reduction, starting from a three-dimensional theory of adhesive contact between two plates.

We base our analysis on Γ-convergence. The Γ-convergence method to study dimension reduction problems has been introduced, in the static case, by Acerbi, Buttazzo and Percivale [1], for nonlinear elastic strings. This approach has been followed soon by Anzellotti, Baldo, Percivale [3] and Borquin, Ciarlet, Geymonat, Raoult [7] for linear elastic beams and plates. It also led to the first convergence result for nonlinear elastic plates due to Le Dret and Raoult [39] who themselves based their approach on that of [1]. Γ-convergence provides an alternative to the more classical formal asymptotic development methods that, since Ciarlet and Destuynder [12], are based on a variational weak formulation of the problem. The notion of quasi-static evolution in fracture mechanics, as addressed by Francfort and Marigo [17,18], is based on an energy minimization procedure which fits the energetic solution framework of Mielke and Theil [51], for which it is natural to apply Γ-convergence methods.

We confine ourselves to *small strains*. The surface where delamination may occur is assumed to be a-priori prescribed. Furthermore, we restrict our attention to *quasistatic* unidirectional (i.e., healing of the adhesive is not possible) *rate-independent delamination*. We consider a unilateral *Signorini contact*, which is important to prevent (unphysical) delamination by mere compression. In the first part of the paper, we focus on a standard, mode-insensitive delamination, while, in Section 5 we distinguish between various modes of delamination (namely opening vs. shearing). The variational dimension reduction process leads to a *Kirchhoff-Love* model for the plate. The case of a "vertically" positioned delaminating surface has been studied in [21] and, using a Barenblatt-like cohesive crack surface energy, also in [20]. For a static delamination on a generally-positioned delamination surface in Kirchhoff-Love plates, we refer to [29,30].
Fig. 1. *Illustration of the geometry and of the notation.*
Left: a 3D thin plate-like body undergoing delamination on a prescribed surface Γ_{C}.
Right: 2D plates obtained for $\varepsilon \to 0$ undergoing delamination.

For notational simplicity, we study the case of only two plates glued together by one delamination surface Γ_{C}, dividing thus a 3-dimensional cylindrical elastic body into two parts occupying respectively the domains Ω_1^ε and Ω_2^ε, cf. Figure 1(left). The generalization of a sandwich laminate composed from $N \geq 3$ domains glued on $N-1$ surfaces is straightforward.

We assume both parts Ω_1^ε and Ω_2^ε to be fixed by Dirichlet boundary conditions on some (non-vanishing) parts of the side boundary, denoted by $\Gamma_{\mathrm{D1}}^\varepsilon$ and $\Gamma_{\mathrm{D2}}^\varepsilon$, respectively; cf. again Figure 1(left). We consider a rather special "cylindrical" case, i.e., in particular the Dirichlet parts of the boundary are positioned vertically, while the delaminating surface Γ_{C} is horizontal. More precisely,

$$\Omega_1^\varepsilon := \Gamma_{\mathrm{C}} \times \Big(-\frac{\varepsilon h_1}{2}, 0\Big), \quad \Omega_2^\varepsilon := \Gamma_{\mathrm{C}} \times \Big(0, \frac{\varepsilon h_2}{2}\Big), \quad \Gamma_{\mathrm{D1}}^\varepsilon = \gamma_{\mathrm{D1}} \times \Big(-\frac{\varepsilon h_1}{2}, 0\Big), \quad \Gamma_{\mathrm{D2}}^\varepsilon = \gamma_{\mathrm{D2}} \times \Big(0, \frac{\varepsilon h_2}{2}\Big). \quad (1.1)$$

We will use the abbreviation

$$\Omega^\varepsilon = \Omega_1^\varepsilon \cup \big(\Gamma_{\mathrm{C}} \times \{0\}\big) \cup \Omega_2^\varepsilon = \Gamma_{\mathrm{C}} \times \Big(-\frac{\varepsilon h_1}{2}, \frac{\varepsilon h_2}{2}\Big) \quad \text{and} \quad \Gamma_{\mathrm{D}}^\varepsilon = \Gamma_{\mathrm{D1}}^\varepsilon \cup \Gamma_{\mathrm{D2}}^\varepsilon.$$

The constant parameters h_1 and h_2 are kept to clarify the role played by the thickness of the body in the limit problem. This will allow for the dimensional reduction by letting the aspect ratio ε go to 0. The geometry of the resulted laminated-composite plate (here, for simplicity, composed only of two plates) is then depicted in Figure 1(right).

Throughout the whole article, we will use a rather special general framework, namely that the state, denoted by $q = (u, z)$, and its evolution are governed by a time-dependent stored energy, denoted by $\mathcal{E}$, and a potential of dissipative forces, denoted by $\mathcal{R}$. This potential depends only on the rate $\dot{z}$ of the dissipative component z but not on the state q itself (the so-called associative case) and is positively homogeneous (the so-called rate-independent case). The quasistatic evolution we have in mind is governed by the following Biot's type [5,6] system of *doubly nonlinear* degenerate *parabolic/elliptic variational inclusions*:

$$\partial_u \mathcal{E}(t, u, z) \ni 0 \quad \text{and} \quad \partial \mathcal{R}(\dot{z}) + \partial_z \mathcal{E}(t, u, z) \ni 0, \quad (1.2)$$

where "∂" denotes the usual (partial) subdifferential of convex analysis, according with the fact that, throughout the paper, the functionals $\mathcal{R}(\cdot)$, $\mathcal{E}(t, \cdot, z)$, and $\mathcal{E}(t, u, \cdot)$ are convex.

An important assumption is that $\mathcal{R}$ is degree-1 positively homogeneous, which implies (and even is equivalent to) that the dissipation rate is just the potential of a dissipative force. Also this implies that, if $\mathcal{E}(t, \cdot, \cdot)$ is convex, the conventional weak solutions are basically equivalent (under mild additional temporal regularity assumptions) to so-called *energetic solutions* of the rate-independent system associated to $\mathcal{E}$ and $\mathcal{R}$ with the initial conditions

$$u(0) = u^0 \quad \text{and} \quad z(0) = z^0. \quad (1.3)$$

We consider a fixed time horizon $T > 0$ and denote by $\mathcal{U}$ and $\mathcal{Z}$ the abstract spaces where u and z live, respectively.

Definition 1.1 (Energetic solution). *The process $q = (u, z) : [0, T] \to \mathcal{Q} := \mathcal{U} \times \mathcal{Z}$ is called an* energetic solution *of the initial-value problem given by $(\mathcal{U} \times \mathcal{Z}, \mathcal{E}, \mathcal{R}, u^0, z^0)$ if, beside (1.3), $t \mapsto \partial_t \mathcal{E}(t, q(t)) \in L^1((0, T))$,*

if for all $t \in [0, T]$ we have $\mathcal{E}(t, q(t)) < +\infty$ and if the global stability inequality (1.4a) and the global energy balance (1.4b) are satisfied for all $t \in [0, T]$:

$$\forall \check{q} = (\check{u}, \check{z}) \in \mathcal{Q} : \qquad \mathcal{E}(t, q(t)) \leq \mathcal{E}(t, \check{q}) + \mathcal{R}(\check{z} - z(t)), \tag{1.4a}$$

$$\mathcal{E}(t, q(t)) + \mathrm{Diss}_{\mathcal{R}}(z, [0, t]) = \mathcal{E}(0, q(0)) + \int_0^t \partial_s \mathcal{E}(s, q(s)) \, \mathrm{d}s \tag{1.4b}$$

with $\mathrm{Diss}_{\mathcal{R}}(z, [0, t]) := \sup \sum_{j=1}^N \mathcal{R}(z(t_j) - z(t_{j-1}))$, where the supremum is taken over all partitions $0 \leq t_0 < t_1 < ... < t_N \leq t$ of $[0, t]$ with $N \in \mathbb{N}$.

If $\mathcal{E}(t, \cdot, \cdot)$ is separately convex but nonconvex, as in this work, then (1.2) and (1.4) are no longer equivalent. The energetic formulation (1.4) then represents a generalized formulation based on a minimum-energy principle competing with the maximum-dissipation principle or rather with Levitas' realizability principle [41], cf. [46, 51, 52]. The main advantages of the energetic-solution concept are that it is derivative-free, i.e., there is no $\partial_u \mathcal{E}$, nor $\partial_z \mathcal{E}$, neither $\dot{z}$ in Definition 1.1, and that it can be handled by Calculus of Variations techniques (in particular variational convergence, as shown in [50] and as exploited also here) as well as strictly linked with direct numerical methods, as shown in [49]. For its application to delamination, namely to the problem determined below by $(\mathcal{U} \times \mathcal{Z}, \mathsf{E}_\varepsilon, \mathsf{R}_\varepsilon^d, \mathsf{q}_\varepsilon^0)$, with numerical implementation and computational simulations we refer to [35, 56, 59]. Roughly speaking, energetic solutions tempt to evolve as soon as it is energetically convenient. This may, however, not be exactly always in full agreement with the response of real systems involving some other rate-dependent phenomena. Therefore, in spite of these theoretical and computational arguments supporting the energetic-solution concept, there are also some other concepts of solutions that are sometimes applicable and successfully competing with energetic solutions, cf. also [16, 47, 48, 53] for a comparison with other notions in general, and, e.g., [10, 31–33, 36, 37, 54, 55] in the context of crack propagation, or, e.g., [4, 13, 14] in the context of plasticity. Moreover, we refer to e.g. [8, 9, 27, 28, 40] for some more classical approaches used in the engineering literature. The validity of the dimension reduction results presented here for the energetic-solution concept is not obvious in the case of other solution concepts.

One should emphasize the quite essential differences from a delamination surface being positioned "vertically", which was investigated in [20, 21]. In those papers the vertically positioned surface scaled as ε, in contrast to the horizontally positioned Γ_C considered in this paper. Due to this fact, the energies have here a different scaling, cf. (3.6) and (3.10) below. Another difference due to the "sandwich" position of the contact surface is that the delamination parameter z is now independent of x_3, which means that here it will not be rescaled and remains the same also for the limit 2D problem. Moreover, [21] considers also a delamination model obtained for $\kappa_\tau = \kappa_\nu = \kappa \to +\infty$, cf. (3.6). This leads to a so-called brittle, Griffith-type delamination model, but such a limit passage is not clear in the framework of the present work.

It is worth notice that a related interesting issue concernes the study of the singularities developed by the energetic solutions, see for instance [2, 15, 25, 34, 58], including their propagation in the quasi-static evolution process. Nevertheless this kind of analysis relies on completely different techniques and for this reason it is out of the purposes of the present paper.

The paper is organized as follows: In Sect. 2 we formulate the original 3-dimensional problem. In Sect. 3 we specify the scaling we want to consider, rescale the original problem to a fixed 3-dimensional domain, and state the convergence result. In Sect. 4 we formulate a 2-dimensional variant of the limit problem. Eventually, Sect. 5 investigates a generalization allowing to distinguish among different delamination modes, namely opening from shearing or from mixing of both.

We will use the standard notation as far as the function spaces concerns: C^k for the space of functions with continuous k-th derivative, L^p for Lebesgue spaces and $W^{k,p}$ for Sobolev spaces. Given a vector function v, the α-th component of v, usually denoted by v_α, will be sometimes denoted also with $[v]_\alpha$.

Considering the continuous parameter $\varepsilon \to 0+$, cf. Fig. 1(left), for notational simplicity and without any confusion, when speaking about a sequence we have in mind a countable number of ε's, ε_n, converging to 0. So, when we write $\mathcal{E}_\varepsilon$ in fact we have in mind $\mathcal{E}_{\varepsilon_n}$, and so on. We immediately make use of this notation in introducing the concept of *uniformly stable sequence* which plays a basic role in stating and proving our convergence results and in particular in the construction of a so-called *mutual recovery sequence*, cf. (3.21b) below.

3

As in Definition 1.1, we consider $\mathcal{Q} = \mathcal{U} \times \mathcal{Z}$ and set $q = (u, z)$, and we shall write, for instance, (t, q) in place of (t, u, z). For $t \in [0, T]$ and $\varepsilon \geq 0$, the *sets of stable states* $\mathcal{S}_\varepsilon(t)$ is defined as

$$\mathcal{S}_\varepsilon(t) := \big\{ q \in \mathcal{Q} : \mathcal{E}_\varepsilon(t, q) < +\infty \text{ and } \mathcal{E}_\varepsilon(t, q) \leq \mathcal{E}_\varepsilon(t, \check{q}) + \mathcal{R}_\varepsilon(\check{z} - z) \ \forall \check{q} \in \mathcal{Q} \big\}. \tag{1.5}$$

For ε fixed, we shall say that a sequence $(t_n, q_n)_{n \in \mathbb{N}}$ is *stable* with respect to $\mathcal{E}_\varepsilon$ and $\mathcal{R}_\varepsilon$ if

$$q_n \in \mathcal{S}_\varepsilon(t_n) \quad \text{and} \quad \sup_{n \in \mathbb{N}} \mathcal{E}_\varepsilon(t_n, q_n) < +\infty. \tag{1.6}$$

We shall say that a sequence $(t_\varepsilon, q_\varepsilon)$ is *uniformly stable* with respect to the collection $(\mathcal{E}_\varepsilon)_{\varepsilon > 0}$ and $(\mathcal{R}_\varepsilon)_{\varepsilon > 0}$ if

$$q_\varepsilon \in \mathcal{S}_\varepsilon(t_\varepsilon) \quad \text{and} \quad \sup_\varepsilon \mathcal{E}_\varepsilon(t_\varepsilon, q_\varepsilon) < +\infty. \tag{1.7}$$

To be formal we should have put ε_n in place of ε everywhere in the definition above. Hence the notion of uniformly stable sequence depends on which sequence of functionals it is referred to. According to the mentioned shorthand convention, in the sequel we omit to state explicitly this reference when it can be easily deduced from the context.

2 Delamination of the adhesive unilateral contact in 3D bodies

In this section we consider a Fremond's [22–24] type model for delamination in 3D bodies which is the starting point of our asymptotic analysis and which has been discussed, for instance, in [62]. In particular, the existence of an energetic solution has been proven in [35] where also a numerical analysis of some model examples is performed. In [61] this model has been characterized as a modification (or, in fact, regularization) of the *Griffith concept* [26], based on the hypothesis that the two parts of the body can be delaminated just by a phenomenologically prescribed specific energy a_ε (in physical units J/m^2).

For later purposes, we indicate the dependence on the thickness parameter ε, even if it will be considered fixed throughout this whole Section 2. Moreover, a delamination parameter $z : \Gamma_{\mathrm{C}} \to [0, 1]$ is involved, representing the fraction of fixed adhesive: $z(x) = 0$ means complete delamination, $z(x) = 1$ means perfect integrity and, for instance, $z(x) = \frac{1}{2}$ means that 50% of the adhesive is debonded at $x \in \Gamma_{\mathrm{C}}$. This model is determined by the stored energy $\widetilde{\mathcal{E}}_\varepsilon$ and the dissipation energy $\mathcal{R}_\varepsilon$. The stored energy $\widetilde{\mathcal{E}}_\varepsilon$, depending on the time t, on the displacement u, and on the delamination parameter z, is given by

$$\widetilde{\mathcal{E}}_\varepsilon(t, u, z) = \begin{cases} \dfrac{1}{2} \displaystyle\int_{\Omega_1^\varepsilon \cup \Omega_2^\varepsilon} \mathbb{C}e(u){:}e(u) - 2f^\varepsilon(t){\cdot}u \, \mathrm{d}x + \int_{\Gamma_{\mathrm{C}}} zQ^\varepsilon(\llbracket u \rrbracket) \, \mathrm{d}\mathscr{H}^2 & \text{if } (u, z) \in \mathcal{A}_\varepsilon^{\mathrm{ad}}(w_{\mathrm{D}}^\varepsilon(t)), \\ +\infty & \text{else,} \end{cases} \tag{2.1}$$

where $e(u) := \frac{1}{2}(\nabla u)^\top + \frac{1}{2}\nabla u$ is the small-strain tensor and $\mathbb{C}$ is the tensor of elastic moduli which may depend on x in the following way:

$$\mathbb{C} = \mathbb{C}(x) = \begin{cases} \mathbb{C}^{(1)} & \text{if } x \in \Omega_1, \\ \mathbb{C}^{(2)} & \text{if } x \in \Omega_2. \end{cases} \tag{2.2}$$

The symbol $\llbracket \cdot \rrbracket$ in (2.1) denotes the jump across the surface Γ_{C} and $Q^\varepsilon : \mathbb{R}^3 \to \mathbb{R}$ is a positive-definite quadratic form allowing for an anistropy of the adhesive to be specified later, cf. (3.6), and the admissible domain dependent on the prescribed Dirichlet condition $w_{\mathrm{D}}^\varepsilon$ is

$$\mathcal{A}_\varepsilon^{\mathrm{ad}}(w_{\mathrm{D}}) = \big\{ (u, z) \in W^{1,2}(\Omega_1^\varepsilon \cup \Omega_2^\varepsilon; \mathbb{R}^3) \times L^\infty(\Gamma_{\mathrm{C}}) \ : \ u = w_{\mathrm{D}} \text{ on } \Gamma_{\mathrm{D}}^\varepsilon, \ \ 0 \leq z \leq 1, \ \ \llbracket u \rrbracket {\cdot} \nu \geq 0 \text{ on } \Gamma_{\mathrm{C}} \big\},$$

where ν is the normal to Γ_{C} (i.e., the unit vector of the axis x_3, see Fig.1). Finally,

$$\mathcal{R}_\varepsilon(\dot{z}) := \begin{cases} \displaystyle\int_{\Gamma_{\mathrm{C}}} a_\varepsilon |\dot{z}| \, \mathrm{d}\mathscr{H}^2 & \text{if } \dot{z} \leq 0 \text{ on } \Gamma_{\mathrm{C}}, \\ +\infty & \text{else.} \end{cases} \tag{2.3}$$

4

The ε-dependence of the body forces $f^\varepsilon \in C^1([0,T]; L^2(\Omega^\varepsilon; \mathbb{R}^3))$ and the boundary displacements $w_{\mathrm{D}}^\varepsilon \in C^1([0,T]; H^{1/2}(\overline{\Gamma_{\mathrm{D}}^\varepsilon}; \mathbb{R}^3))$ will be precised in Section 3.1, cf. (3.3)–(3.5).

We assume that $\mathbb{C}^{(\ell)}$ are fourth-order positive-definite tensors, i.e.,

$$\mathbb{C}^{(\ell)}e{:}e \geq c|e|^2, \qquad \ell = 1, 2, \tag{2.4}$$

for every symmetric matrix $e \in \mathbb{R}^{3\times 3}_{\mathrm{sym}}$ and with some $c > 0$ and that

$$a_\varepsilon(x) \geq a_{\varepsilon,\min} \tag{2.5}$$

for a suitable constant $a_{\varepsilon,\min} > 0$ (depending on ε, but not on x) and $\mathscr{H}^2$-a.e. $x \in \Gamma_{\mathrm{C}}$. Moreover, we assume the following usual symmetry properties

$$\mathbb{C}^{(\ell)}_{ijkl} = \mathbb{C}^{(\ell)}_{ijlk} = \mathbb{C}^{(\ell)}_{klij}, \qquad i, j, k, l = 1, 2, 3, \quad \ell = 1, 2, \tag{2.6}$$

and that the material has a monoclinic symmetry with respect to the (x_1, x_2)-plane, which implies

$$\mathbb{C}^{(\ell)}_{\alpha\beta\gamma 3} = \mathbb{C}^{(\ell)}_{\alpha 333} = 0, \qquad \alpha, \beta, \gamma = 1, 2, \quad \ell = 1, 2. \tag{2.7}$$

We restrict to the monoclinic symmetry for simplicity. In the absence of delamination, under this assumption, the limit problem decouples into two separate problems: one consisting in the in-plane equilibrium equations and the other for the out-of-plane equations.

It should be noted that Definition 1.1 does not apply directly to the problem involving $\widetilde{\mathcal{E}}_{\varepsilon,\kappa}$ if the Dirichlet loading $w_{\mathrm{D}}^\varepsilon$ varies in time because the time derivative in (1.4b) is not well defined. To handle it, one must transform the problem into a time-independent Dirichlet loading problem. In this way, we consider a prolongation $u_{\mathrm{D}}^\varepsilon(t)$ of $w_{\mathrm{D}}^\varepsilon(t)$ to the whole Ω^ε satisfying

$$\llbracket u_{\mathrm{D}}^\varepsilon(t) \rrbracket = 0 \qquad \text{a.e. on } \Gamma_{\mathrm{C}} \text{ for a.a. } t, \tag{2.8}$$

and then, instead of (2.1), we consider

$$\mathcal{E}_\varepsilon(t, u, z) = \begin{cases} \dfrac{1}{2} \displaystyle\int_{\Omega_1^\varepsilon \cup \Omega_2^\varepsilon} \mathbb{C}e(u + u_{\mathrm{D}}^\varepsilon(t)){:}e(u + u_{\mathrm{D}}^\varepsilon(t)) - 2f^\varepsilon(t){\cdot}(u + u_{\mathrm{D}}^\varepsilon(t)) \, \mathrm{d}x \\ \qquad\qquad\qquad\qquad + \displaystyle\int_{\Gamma_{\mathrm{C}}} zQ^\varepsilon(\llbracket u \rrbracket) \, \mathrm{d}\mathscr{H}^2 \qquad \text{if } (u, z) \in \mathcal{A}_\varepsilon^{\mathrm{ad}}, \\ +\infty \qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\quad \text{else,} \end{cases} \tag{2.9}$$

where $\mathcal{A}_\varepsilon^{\mathrm{ad}} := \mathcal{A}_\varepsilon^{\mathrm{ad}}(0)$. The spaces $\mathcal{U}$, $\mathcal{Z}$ and $\mathcal{Q}$ in Definition 1.1 are as

$$\mathcal{U}_\varepsilon = \big\{ u \in W^{1,2}(\Omega_1^\varepsilon \cup \Omega_2^\varepsilon; \mathbb{R}^3) : \ u = 0 \text{ on } \Gamma_{\mathrm{D}}^\varepsilon \big\}, \ \mathcal{Z} = \big\{ z \in L^\infty(\Gamma_{\mathrm{C}}) : \ 0 \leq z \leq 1 \text{ on } \Gamma_{\mathrm{C}} \big\}, \ \mathcal{Q} = \mathcal{U}_\varepsilon \times \mathcal{Z}; \tag{2.10}$$

here both $\mathcal{U}_\varepsilon$ and $\mathcal{Z}$ are even subsets of Banach spaces and we will consider them equipped with standard norm, weak, and weak* topologies. Having an energetic solution $(u_\varepsilon, z_\varepsilon)$ to the problem $(\mathcal{U}_\varepsilon \times \mathcal{Z}_\varepsilon, \mathcal{E}_\varepsilon, \mathcal{R}_\varepsilon, q^0)$ according to Definition 1.1, the shifted solution $(u_\varepsilon + u_{\mathrm{D}}^\varepsilon, z_\varepsilon)$ will serve as an energetic solution to the original problem involving $\widetilde{\mathcal{E}}_\varepsilon$. We will thus deal only with the transformed problems. Note that here it is desirable to accept that Γ_{C} and $\Gamma_{\mathrm{D}}^\varepsilon$ are not far from each other (i.e., their closures may not be disjoint), which requires the compatibility of the boundary condition (2.8). More specifically, we assume

$$w_{\mathrm{D}}^\varepsilon \in C^1([0,T]; H^{1/2}(\overline{\Gamma_{\mathrm{D}}^\varepsilon}; \mathbb{R}^3)), \tag{2.11}$$

which, in particular, ensures the existence of a prolongation $u_{\mathrm{D}}^\varepsilon \in C^1([0,T]; W^{1,2}(\overline{\Omega^\varepsilon}; \mathbb{R}^3))$ satisfying (2.8) for all t.

The following proposition can be proven by applying general existence results on energetic solutions, cf. [46, 51], and of course follows also by [35, Proposition 3.3].

Proposition 2.1. *Let $\varepsilon > 0$ be fixed, assume (2.11), and let $q^0 = (u^0, z^0)$ be stable at time $t = 0$, that is*

$$\mathcal{E}_\varepsilon(0, q^0) < +\infty \quad \& \quad \mathcal{E}_\varepsilon(0, q^0) \leq \mathcal{E}_\varepsilon(0, \check{q}) + \mathcal{R}_\varepsilon(\check{z} - z^0) \quad \text{for all } \check{q} = (\check{u}, \check{z}) \in \mathcal{Q}. \tag{2.12}$$

Then the energetic solution $(u_\varepsilon, z_\varepsilon)$ to the problem $(\mathcal{U}_\varepsilon \times \mathcal{Z}, \mathcal{E}_\varepsilon, \mathcal{R}_\varepsilon, q^0)$ does exist.

3 Dimension reduction

In this section, we rescale the family of the problems on the domains $\Omega_1^\varepsilon \cup \Omega_2^\varepsilon$ parameterized by $\varepsilon > 0$ to a single auxiliary domain arising for $\varepsilon = 1$, denoted by $\Omega_1 \cup \Omega_2$, and analyze the convergence as $\varepsilon \to 0$.

3.1 The rescaled problem

To perform the dimension reduction it is convenient to make a change of variables in order to work on domains independent of ε. There are lot of similarities with [21, Sect.3-5] so that we expose it only briefly. Beside $\Omega_1 := \Omega_1^1$, $\Omega_2 := \Omega_2^1$, let also $\Gamma_{D1} := \Gamma_{D1}^1$ and $\Gamma_{D2} := \Gamma_{D2}^1$, so that $\Omega := \Omega^1$ and $\Gamma_D := \Gamma_D^1$. For any $\varepsilon > 0$, let $p_\varepsilon : \overline{\Omega_1 \cup \Omega_2} \to \overline{\Omega_1^\varepsilon \cup \Omega_2^\varepsilon}$ be defined by

$$p_\varepsilon(x_1, x_2, x_3) := (x_1, x_2, \varepsilon x_3).$$

The variables on the fixed domain, $\Omega_1 \cup \Omega_2$, will be denoted by using the Sans font. Thus for $u \in W^{1,2}(\Omega_1^\varepsilon \cup \Omega_2^\varepsilon; \mathbb{R}^3)$, let $\mathsf{u} \in W^{1,2}(\Omega_1 \cup \Omega_2; \mathbb{R}^3)$ be defined by

$$\begin{aligned} \mathsf{u}_\alpha &:= \frac{1}{\varepsilon} u_\alpha \circ p_\varepsilon, \ \ \alpha = 1, 2, \\ \mathsf{u}_3 &:= u_3 \circ p_\varepsilon. \end{aligned} \tag{3.1}$$

Of course, z is not scaled and thus it remains in Italic font. With this notation we have

$$\frac{1}{\varepsilon} e(u) \circ p_\varepsilon = \begin{pmatrix} e(\mathsf{u})_{\alpha\beta} & \frac{1}{\varepsilon} e(\mathsf{u})_{\alpha 3} \\ \frac{1}{\varepsilon} e(\mathsf{u})_{3\beta} & \frac{1}{\varepsilon^2} e(\mathsf{u})_{33} \end{pmatrix} =: e^\varepsilon(\mathsf{u}). \tag{3.2}$$

In order to keep the displacements bounded, we need to rescale the forces and the boundary conditions with ε. We assume that there exists $\mathsf{f} \in C^1([0, T]; L^2(\Omega; \mathbb{R}^3))$ such that

$$\varepsilon^{\ell_\tau + 1} \mathsf{f}_\alpha(t) = f_\alpha^\varepsilon(t) \circ p_\varepsilon, \ \ \alpha = 1, 2, \quad \text{and} \quad \varepsilon^{\ell_\nu + 2} \mathsf{f}_3(t) = f_3^\varepsilon(t) \circ p_\varepsilon, \qquad \ell_\tau, \ell_\nu \geq 0. \tag{3.3}$$

Concerning the boundary conditions we need to require that $e^\varepsilon(\mathsf{u}_D^\varepsilon(t))$ is bounded in $L^2(\Omega_1 \cup \Omega_2; \mathbb{R}^{3 \times 3})$, where we have set $[\mathsf{u}_D^\varepsilon]_\alpha := \frac{1}{\varepsilon} [u_D^\varepsilon]_\alpha \circ p_\varepsilon$ and $[\mathsf{u}_D^\varepsilon]_3 := [u_D^\varepsilon]_3 \circ p_\varepsilon$. The simplest way to fulfill this requirement is to pose $\mathsf{u}_D^\varepsilon = \mathsf{u}_D$, with u_D satisfying the following Kirchhoff-Love assumption which is fundamental in plate theory, cf. [11]:

$$\begin{aligned} [\mathsf{u}_D]_\alpha(t, x_1, x_2, x_3) &:= [\rho_D]_\alpha(t, x_1, x_2) - x_3 \frac{\partial}{\partial x_\alpha} \xi_D(t, x_1, x_2), \qquad \alpha = 1, 2, \\ [\mathsf{u}_D]_3(t, x_1, x_2, x_3) &:= \xi_D(t, x_1, x_2), \end{aligned} \tag{3.4}$$

where $\xi_D \in C^1([0, T]; W^{2,2}(\Omega))$ and $\rho_D \in C^1([0, T]; W^{1,2}(\Omega; \mathbb{R}^2))$. Let us remark that with this choice we have

$$e^\varepsilon(\mathsf{u}_D^\varepsilon)_{i3} = 0, \quad i = 1, 2, 3, \tag{3.5}$$

hence, in particular, $e^\varepsilon(\mathsf{u}_D^\varepsilon) = e^\varepsilon(\mathsf{u}_D) = e(\mathsf{u}_D)$ for any ε.

The quadratic form used in (2.1), possibly scaling anisotropically the elastic response of the adhesive, is considered, for any $\varepsilon > 0$, to be of the form, see for instance Tavara et al. [63],

$$Q^\varepsilon(s) := \varepsilon^{q_\tau + 1} \kappa_\tau |s_\tau|^2 + \varepsilon^{q_\nu + 3} \kappa_\nu |s_\nu|^2, \qquad q_\tau, q_\nu \in \mathbb{R}, \ \kappa_\tau, \kappa_\nu > 0, \tag{3.6}$$

where $s = (s_\tau, s_\nu) \in \mathbb{R}^2 \times \mathbb{R}$.

Denoting by $[\![u]\!]_\tau := ([\![u_1]\!], [\![u_2]\!])$ and $[\![u]\!]_\nu := [\![u_3]\!]$, respectively, the tangential and the normal jump of the displacement across the delamination surface Γ_C, and using the relation (3.1) between $u \in W^{1,2}(\Omega_1^\varepsilon \cup \Omega_2^\varepsilon; \mathbb{R}^3)$ and $\mathsf{u} \in W^{1,2}(\Omega_1 \cup \Omega_2; \mathbb{R}^3)$, for any $\varepsilon > 0$ we get

$$Q^\varepsilon([\![u]\!]) = \varepsilon^{q_\tau + 3} \kappa_\tau |[\![\mathsf{u}]\!]_\tau|^2 + \varepsilon^{q_\nu + 3} \kappa_\nu |[\![\mathsf{u}]\!]_\nu|^2 = \varepsilon^3 \mathsf{Q}^\varepsilon([\![\mathsf{u}]\!])$$

having defined

$$\mathsf{Q}^\varepsilon\big(\llbracket \mathsf{u}\rrbracket\big) := \varepsilon^{q_\tau}\kappa_\tau\big|\llbracket \mathsf{u}\rrbracket_\tau\big|^2 + \varepsilon^{q_\nu}\kappa_\nu\big|\llbracket \mathsf{u}\rrbracket_\nu\big|^2. \tag{3.7}$$

The functional Q^ε (as well as Q^ε) modulates differently the components of the jump of u. The different scalings take into account the different rigidity in the in-plane and in the out-of-plane directions of the cylinders of height εh_ℓ, $\ell = 1, 2$.

It is convenient to do the same also with the body force. Recalling (3.3) and using again (3.1) we observe that

$$f^\varepsilon\cdot(u+u_{\mathrm{D}}^\varepsilon) = \sum_{\alpha=1,2}\varepsilon^{\ell_\tau+2}\mathsf{f}_\alpha^\varepsilon(\mathsf{u}_\alpha+[\mathsf{u}_{\mathrm{D}}]_\alpha) + \varepsilon^{\ell_\nu+2}\mathsf{f}_3^\varepsilon(\mathsf{u}_3+[\mathsf{u}_{\mathrm{D}}]_3) =: \varepsilon^2 \mathsf{f}^\varepsilon\cdot(\mathsf{u}+\mathsf{u}_{\mathrm{D}}),$$

having defined

$$\mathsf{f}^\varepsilon := (\varepsilon^{\ell_\tau}\mathsf{f}_1, \varepsilon^{\ell_\tau}\mathsf{f}_2, \varepsilon^{\ell_\nu}\mathsf{f}_3).$$

For $(u,z)\in\mathcal{A}_\varepsilon^{\mathrm{ad}}$ we have

$$\begin{aligned}
\mathcal{E}_\varepsilon(t,u,z) &= \frac{1}{2}\int_{\Omega_1^\varepsilon\cup\Omega_2^\varepsilon}\mathbb{C}e(u+u_{\mathrm{D}}^\varepsilon(t)){:}e(u+u_{\mathrm{D}}^\varepsilon(t)) - 2f^\varepsilon(t)\cdot(u+u_{\mathrm{D}}^\varepsilon(t))\,\mathrm{d}x + \int_{\Gamma_{\mathrm{C}}}zQ^\varepsilon\big(\llbracket u\rrbracket\big)\,\mathrm{d}\mathscr{H}^2 \\
&= \frac{\varepsilon^3}{2}\int_{\Omega_1\cup\Omega_2}\mathbb{C}e^\varepsilon(\mathsf{u}+\mathsf{u}_{\mathrm{D}}(t)){:}e^\varepsilon(\mathsf{u}+\mathsf{u}_{\mathrm{D}}(t)) - 2\mathsf{f}^\varepsilon(t)\cdot(\mathsf{u}+\mathsf{u}_{\mathrm{D}}(t))\,\mathrm{d}x + \varepsilon^3\int_{\Gamma_{\mathrm{C}}}z\mathsf{Q}^\varepsilon\big(\llbracket \mathsf{u}\rrbracket\big)\,\mathrm{d}\mathscr{H}^2 \\
&= \varepsilon^3\mathsf{E}_\varepsilon(t,\mathsf{u},z),
\end{aligned} \tag{3.8}$$

where we used

$$\mathsf{E}_\varepsilon(t,\mathsf{u},z) := \begin{cases}\dfrac{1}{2}\displaystyle\int_{\Omega_1\cup\Omega_2}\mathbb{C}e^\varepsilon(\mathsf{u}+\mathsf{u}_{\mathrm{D}}(t)){:}e^\varepsilon(\mathsf{u}+\mathsf{u}_{\mathrm{D}}(t)) - 2\mathsf{f}^\varepsilon(t)\cdot(\mathsf{u}+\mathsf{u}_{\mathrm{D}}(t))\,\mathrm{d}x \\
\qquad\qquad\qquad\qquad\qquad\qquad + \displaystyle\int_{\Gamma_{\mathrm{C}}}z\mathsf{Q}^\varepsilon\big(\llbracket \mathsf{u}\rrbracket\big)\,\mathrm{d}\mathscr{H}^2 & \text{if } (\mathsf{u},z)\in\mathsf{A}^{\mathrm{ad}}, \\[6pt]
+\infty & \text{else},\end{cases} \tag{3.9}$$

with

$$\mathsf{A}^{\mathrm{ad}} := \big\{(\mathsf{u},z)\in W^{1,2}(\Omega_1\cup\Omega_2;\mathbb{R}^3)\times L^\infty(\Gamma_{\mathrm{C}}):\ \mathsf{u} = 0 \text{ on } \Gamma_{\mathrm{D}},\ \ 0\le z\le 1,\ \ \llbracket \mathsf{u}\rrbracket_\nu\ge 0 \text{ on } \Gamma_{\mathrm{C}}\big\}.$$

The energy functional has been scaled by dividing by ε^3, as it is conventionally done in linear elasticity. On the other hand, it is easy to see that any other choice turns out to be equivalent. Indeed, since the bulk energy is a quadratic form of u, one can always reduce to this case by suitably re-scaling the displacements. Similarly we rescale the dissipation energy; we assume that there exist a measurable function $\mathsf{a}\in L^1(\Gamma_{\mathrm{C}})$ and $d\in\mathbb{R}$ such that

$$\frac{a_\varepsilon}{\varepsilon^{3+d}} = \mathsf{a} \tag{3.10}$$

for any ε, so that

$$\mathcal{R}_\varepsilon(\dot{z}) = \varepsilon^3\mathsf{R}_\varepsilon^d(\dot{z}) \tag{3.11}$$

where

$$\mathsf{R}_\varepsilon^d(\dot{z}) := \begin{cases}\varepsilon^d\displaystyle\int_{\Gamma_{\mathrm{C}}}\mathsf{a}|\dot{z}|\,\mathrm{d}\mathscr{H}^2 & \text{if } \dot{z}\le 0 \text{ on } \Gamma_{\mathrm{C}}, \\[6pt]
+\infty & \text{else}.\end{cases} \tag{3.12}$$

The choice $d = 0$ is the one that yields the same scaling of the stored energy, and only in this case we expect to obtain a non-trivial dissipation in the limit problem (see Liero and Mielke [43, Remark 2.1] for a justification "a priori" of this choice). Referring to (2.5), we also assume that $a_{\varepsilon,\min} = \varepsilon^{3+d}\mathsf{a}_{\min}$ for a suitable constant $\mathsf{a}_{\min} > 0$ so that $\mathsf{a}(x)\ge\mathsf{a}_{\min}$ for $\mathscr{H}^2$-a.e. $x\in\Gamma_{\mathrm{C}}$.

To conclude this section, it is worth notice that the dissipation energy R_ε^d induces the following dissipation distance

$$\mathcal{D}_\varepsilon^d(z_1,z_2) := \mathsf{R}_\varepsilon^d(z_2-z_1).$$

Moreover, concerning the notation used in Definition 1.1, we have that $\mathrm{Diss}_{\mathsf{R}_\varepsilon^d}(z,[0,t]) = \mathcal{D}_\varepsilon^d(z(0)-z(t))$.

3.2 The limit problem

It is further useful to introduce the following "reduced" tensor of elastic moduli

$$\mathbb{C}^0_{\alpha\beta\gamma\delta} := \mathbb{C}_{\alpha\beta\gamma\delta} - \frac{\mathbb{C}_{\alpha\beta33}\mathbb{C}_{\gamma\delta33}}{\mathbb{C}_{3333}}, \qquad \alpha, \beta, \gamma, \delta = 1, 2. \tag{3.13}$$

Let us remark (see also [1]) that, when setting $g(e) := \frac{1}{2}\mathbb{C}e{:}e$ for $e \in \mathbb{R}^{3\times3}_{\mathrm{sym}}$, under assumptions (2.6) and (2.7) one has

$$\frac{1}{2}\mathbb{C}^0\tilde{e}{:}\tilde{e} = \min_{\eta\in\mathbb{R}^2, \rho_3\in\mathbb{R}} g\begin{pmatrix} \tilde{e} & \eta \\ \eta^\top & \rho_3 \end{pmatrix} \qquad \text{for every } \tilde{e} \in \mathbb{R}^{2\times2}_{\mathrm{sym}}, \tag{3.14}$$

where the minimum is achieved for $\eta = 0$ and $\rho_3 = -\sum_{\alpha,\beta=1}^2 \mathbb{C}_{33\alpha\beta}\tilde{e}_{\alpha\beta}/\mathbb{C}_{3333}$. Of course, $\mathbb{C}^0$ depends on x_3 as $\mathbb{C}$ does, cf. (2.2). Moreover, let us denote by $\tilde{e}(\mathsf{u})$ the 2×2-matrix with components

$$\tilde{e}(\mathsf{u})_{\alpha\beta} := e(\mathsf{u})_{\alpha\beta}, \quad \alpha, \beta = 1, 2.$$

Before we can write the expected limit energy, it remains to introduce the quadratic form

$$\mathsf{Q}^0(s) := 1_0(q_\tau)\kappa_\tau|s_\tau|^2 + 1_0(q_\nu)\kappa_\nu|s_\nu|^2, \quad s \in \mathbb{R}^2 \times \mathbb{R}, \tag{3.15}$$

and the vector field

$$\mathsf{f}^0 := \left(1_0(\ell_\tau)\mathsf{f}_1, \, 1_0(\ell_\tau)\mathsf{f}_2, \, 1_0(\ell_\nu)\mathsf{f}_3 \right), \tag{3.16}$$

where $1_0(r)$ takes the value 1 if $r = 0$ and is 0 otherwise. Let us remark that the choice $q_\tau = q_\nu = 0$, $\kappa_\tau = \kappa_\nu = \kappa$ gives $\mathsf{Q}^0(\llbracket\mathsf{u}\rrbracket) = \kappa|\llbracket\mathsf{u}\rrbracket|^2$.

Then we define

$$\mathsf{E}_0(t, \mathsf{u}, z) := \begin{cases} \dfrac{1}{2}\displaystyle\int_{\Omega_1\cup\Omega_2} \mathbb{C}^0\tilde{e}(\mathsf{u}+\mathsf{u}_{\mathrm{D}}(t)){:}\tilde{e}(\mathsf{u}+\mathsf{u}_{\mathrm{D}}(t)) \\ \qquad -2\mathsf{f}^0(t)\cdot(\mathsf{u}+\mathsf{u}_{\mathrm{D}}(t))\,\mathrm{d}x + \displaystyle\int_{\Gamma_{\mathrm{C}}} z\mathsf{Q}^0(\llbracket\mathsf{u}\rrbracket)\,\mathrm{d}\mathscr{H}^2 & \text{if } (\mathsf{u}, z) \in \mathsf{A}^{\mathrm{ad}}_{\mathrm{KL}}, \\ +\infty & \text{else,} \end{cases} \tag{3.17}$$

where

$$\mathsf{A}^{\mathrm{ad}}_{\mathrm{KL}} = \left\{ (\mathsf{u}, z) \in \mathsf{A}^{\mathrm{ad}} \; : \; \mathsf{u} \in W^{1,2}_{\mathrm{KL}}(\Omega_1\cup\Omega_2; \mathbb{R}^3) \text{ and } z\llbracket\mathsf{u}\rrbracket_\sigma = 0 \text{ a.e. on } \Gamma_{\mathrm{C}} \text{ if } q_\sigma < 0 \, (\sigma = \tau, \nu) \right\},$$

and where $W^{1,2}_{\mathrm{KL}}(\Omega_1\cup\Omega_2; \mathbb{R}^3)$ stands for the space of Kirchhoff-Love displacements

$$W^{1,2}_{\mathrm{KL}}(\Omega_1\cup\Omega_2; \mathbb{R}^3) := \left\{ \mathsf{u} \in W^{1,2}(\Omega_1\cup\Omega_2; \mathbb{R}^3) : \, e(\mathsf{u})_{i3} = 0 \text{ for } i = 1, 2, 3 \right\}. \tag{3.18}$$

Finally, we define

$$\mathsf{R}^d_0 = \begin{cases} \begin{cases} \displaystyle\int_{\Gamma_{\mathrm{C}}} \mathsf{a}|\dot{z}|\,\mathrm{d}\mathscr{H}^2 & \text{if } \dot{z} \leq 0 \text{ on } \Gamma_{\mathrm{C}}, \\ +\infty & \text{else,} \end{cases} & \text{if } d = 0, \\[12pt] \begin{cases} 0 & \text{if } \dot{z} \leq 0 \text{ on } \Gamma_{\mathrm{C}}, \\ +\infty & \text{else} \end{cases} & \text{if } d > 0, \\[12pt] \begin{cases} 0 & \text{if } \dot{z} = 0 \text{ on } \Gamma_{\mathrm{C}}, \\ +\infty & \text{else,} \end{cases} & \text{if } d < 0. \end{cases} \tag{3.19}$$

The evolution problems will be considered on the spaces

$$\mathcal{U} = \left\{ \mathsf{u} \in W^{1,2}(\Omega_1\cup\Omega_2; \mathbb{R}^3) : \, \mathsf{u} = 0 \text{ on } \Gamma_{\mathrm{D}} \right\} \quad \text{and} \quad \mathcal{Z} \text{ from (2.10).}$$

3.3 Convergence

We discuss here the convergence of energetic solutions associated with the problem $(\mathcal{U} \times \mathcal{Z}, \mathsf{E}_\varepsilon, \mathsf{R}_\varepsilon^d, \mathsf{q}_{0,\varepsilon})$ to energetic solutions associated to the problem $(\mathcal{U} \times \mathcal{Z}, \mathsf{E}_0, \mathsf{R}_0^d, \mathsf{q}_0)$, as $\varepsilon \to 0$. This is done by applying the abstract scheme developed in [50]. Since most of the requirements can be obtained as simple adaptations from [21], we mainly highlight the differences.

The closure of A^{ad} and of the constraints on the jumps, the continuity of the functional representing the work of the body forces, the convergence of the powers

$$\partial_t \mathsf{E}_\varepsilon(t_\varepsilon, \mathsf{u}_\varepsilon, z_\varepsilon) = \int_{\Omega_1 \cup \Omega_2} \mathbb{C}e^\varepsilon(\dot{\mathsf{u}}_{\mathrm{D}}(t_\varepsilon)){:}e^\varepsilon(\mathsf{u}_\varepsilon + \mathsf{u}_{\mathrm{D}}(t_\varepsilon)) - \dot{\mathsf{f}}^\varepsilon(t_\varepsilon){\cdot}(\mathsf{u}_\varepsilon + \mathsf{u}_{\mathrm{D}}(t_\varepsilon)) - \mathsf{f}^\varepsilon(t_\varepsilon){\cdot}\dot{\mathsf{u}}_{\mathrm{D}}(t_\varepsilon)\,\mathrm{d}x \qquad (3.20)$$

to

$$\partial_t \mathsf{E}_0(t, \mathsf{u}, z) = \int_{\Omega_1 \cup \Omega_2} \mathbb{C}^0 \tilde{e}(\dot{\mathsf{u}}_{\mathrm{D}}(t)){:}\tilde{e}(\mathsf{u} + \mathsf{u}_{\mathrm{D}}(t)) - \dot{\mathsf{f}}^0(t){\cdot}(\mathsf{u} + \mathsf{u}_{\mathrm{D}}(t)) - \mathsf{f}^0(t){\cdot}\dot{\mathsf{u}}_{\mathrm{D}}(t)\,\mathrm{d}x,$$

provided that $t_\varepsilon \to t$, $z_\varepsilon \overset{*}{\rightharpoonup} z$ in $L^\infty(\Gamma_{\mathrm{C}})$, $0 \le z_\varepsilon \le 1$ a.e., and $\mathsf{u}_\varepsilon \rightharpoonup \mathsf{u}$ in $W^{1,2}(\Omega_1 \cup \Omega_2; \mathbb{R}^3)$ as $\varepsilon \to 0^+$, with $(t_\varepsilon, \mathsf{u}_\varepsilon, z_\varepsilon)$ being a uniformly stable sequence (cf. (1.7) for E_ε and R_ε^d instead of $\mathcal{E}_\varepsilon$ and $\mathcal{R}_\varepsilon$, respectively) follow by a straightforward adaptation of the proofs of [21, Lemmas 4.1 and 5.2] concerning the case of a transversal delamination surface.

In the next lemma we prove the lower semicontinuity inequality (3.21a) and the existence of a so-called mutual recovery sequence, since these results are not simple adaptations of arguments of [21].

Lemma 3.1. *If $t_\varepsilon \to t$, $z_\varepsilon \overset{*}{\rightharpoonup} z$ in $L^\infty(\Gamma_{\mathrm{C}})$, $0 \le z_\varepsilon \le 1$ a.e., and $\mathsf{u}_\varepsilon \rightharpoonup \mathsf{u}$ in $W^{1,2}(\Omega_1 \cup \Omega_2; \mathbb{R}^3)$ as $\varepsilon \to 0^+$, then*

$$\liminf_{\varepsilon \to 0^+} \mathsf{E}_\varepsilon(t_\varepsilon, \mathsf{u}_\varepsilon, z_\varepsilon) \ge \mathsf{E}_0(t, \mathsf{u}, z), \qquad (3.21\mathrm{a})$$

and, for every $\check{z} \in L^\infty(\Gamma_{\mathrm{C}})$ and every $\check{\mathsf{u}} \in W^{1,2}(\Omega_1 \cup \Omega_2; \mathbb{R}^3)$, there exist $\check{z}_\varepsilon \in \mathcal{Z}$ and $\check{\mathsf{u}}_\varepsilon \in \mathcal{U}$ such that $\check{\mathsf{u}}_\varepsilon \rightharpoonup \check{\mathsf{u}}$ in $W^{1,2}(\Omega_1 \cup \Omega_2; \mathbb{R}^3)$, $\check{z}_\varepsilon \overset{*}{\rightharpoonup} \check{z}$ in $L^\infty(\Gamma_{\mathrm{C}})$ and

$$\limsup_{\varepsilon \to 0} \left[\mathsf{E}_\varepsilon(t_\varepsilon, \check{\mathsf{u}}_\varepsilon, \check{z}_\varepsilon) + \mathsf{R}_\varepsilon^d(\check{z}_\varepsilon - z_\varepsilon) \right] \le \mathsf{E}_0(t, \check{\mathsf{u}}, \check{z}) + \mathsf{R}_0^d(\check{z} - z). \qquad (3.21\mathrm{b})$$

Proof. We first observe that from the convergence assumptions on (z_ε) and (u_ε), where the latter implies the strong convergence of the traces of u_ε on Γ_{C}, it follows that

$$\int_{\Gamma_{\mathrm{C}}} z_\varepsilon \left| [\![\mathsf{u}_\varepsilon]\!]_\sigma \right|^2 \mathrm{d}\mathscr{H}^2 \to \int_{\Gamma_{\mathrm{C}}} z \left| [\![\mathsf{u}]\!]_\sigma \right|^2 \mathrm{d}\mathscr{H}^2, \quad \sigma = \tau, \nu. \qquad (3.22)$$

Let us prove the lower semicontinuity inequality (3.21a). Under the assumption that the liminf on the left-hand side be finite, by the positive definiteness of $\mathbb{C}$ (see (2.4)) and the continuity of w with respect to t and the fact that $\ell_\tau, \ell_\nu \ge 0$, there exists a positive constant C such that

$$\left\| e^\varepsilon(\mathsf{u}_\varepsilon) \right\|_{L^2(\Omega_1 \cup \Omega_2; \mathbb{R}^3)} \le C \qquad (3.23)$$

and

$$\int_{\Gamma_{\mathrm{C}}} z_\varepsilon \varepsilon^{q_\sigma} \left| [\![\mathsf{u}_\varepsilon]\!]_\sigma \right|^2 \mathrm{d}\mathscr{H}^2 \le C, \quad \sigma = \tau, \nu. \qquad (3.24)$$

For any $i = 1, 2, 3$, from (3.23) we get $\left\| e(\mathsf{u}_\varepsilon)_{i3} \right\|_{L^2(\Omega_1 \cup \Omega_2; \mathbb{R}^3)} \le C\varepsilon$, thus, passing to the limit, we obtain $e(\mathsf{u})_{i3} = 0$, which implies $\mathsf{u} \in W_{\mathrm{KL}}^{1,2}(\Omega_1 \cup \Omega_2; \mathbb{R}^3)$.

Rewriting (3.24) as

$$0 \le \int_{\Gamma_{\mathrm{C}}} z_\varepsilon \left| [\![\mathsf{u}_\varepsilon]\!]_\sigma \right|^2 \mathrm{d}\mathscr{H}^2 \le C\varepsilon^{-q_\sigma},$$

if $q_\sigma < 0$, taking the limit as $\varepsilon \to 0^+$ in this inequality we get

$$\int_{\Gamma_{\mathrm{C}}} z \left| [\![\mathsf{u}]\!]_\sigma \right|^2 \mathrm{d}\mathscr{H}^2 = 0$$

9

hence $z[\![u]\!]_\sigma = 0$ $\mathscr{H}^2$-a.e. on Γ_C. Namely, $(u,z) \in \mathsf{A}_{\mathrm{KL}}^{\mathrm{ad}}$ and therefore we have that also the right-hand side in (3.21a) is finite. Using (3.22) in the terms occurring in Q^ε with $q_\sigma = 0$ ($\sigma = \tau, \nu$) and neglecting those in which $q_\sigma \neq 0$, and using moreover the fact that

$$\lim_{\varepsilon \to 0^+} \int_{\Omega_1 \cup \Omega_2} \mathsf{f}^\varepsilon(t) \cdot (\mathsf{u}_\varepsilon + \mathsf{u}_\mathrm{D}(t))\, \mathrm{d}x = \int_{\Omega_1 \cup \Omega_2} \mathsf{f}^0(t) \cdot (\mathsf{u} + \mathsf{u}_\mathrm{D}(t))\, \mathrm{d}x,$$

we argue that it suffices to prove that

$$\liminf_{\varepsilon \to 0^+} \int_{\Omega_1 \cup \Omega_2} \mathbb{C} e^\varepsilon(\mathsf{u}_\varepsilon + \mathsf{u}_\mathrm{D}(t_\varepsilon)) : e^\varepsilon(\mathsf{u}_\varepsilon + \mathsf{u}_\mathrm{D}(t_\varepsilon))\, \mathrm{d}x \geq \int_{\Omega_1 \cup \Omega_2} \mathbb{C}^0 \tilde{e}(\mathsf{u} + \mathsf{u}_\mathrm{D}(t)) : \tilde{e}(\mathsf{u} + \mathsf{u}_\mathrm{D}(t))\, \mathrm{d}x.$$

Since, for $\alpha, \beta = 1, 2$,

$$e^\varepsilon(\mathsf{u}_\varepsilon)_{\alpha\beta} = e(\mathsf{u}_\varepsilon)_{\alpha\beta} \rightharpoonup e(\mathsf{u})_{\alpha\beta} \quad \text{in } L^2(\Omega_1 \cup \Omega_2; \mathbb{R}^3),$$

using property (3.14) and the continuity of u_D with respect to t we find

$$\liminf_{\varepsilon \to 0^+} \int_{\Omega_1 \cup \Omega_2} \mathbb{C} e^\varepsilon(\mathsf{u}_\varepsilon + \mathsf{u}_\mathrm{D}(t_\varepsilon)) : e^\varepsilon(\mathsf{u}_\varepsilon + \mathsf{u}_\mathrm{D}(t_\varepsilon))\, \mathrm{d}x \geq \liminf_{\varepsilon \to 0^+} \int_{\Omega_1 \cup \Omega_2} \mathbb{C}^0 \tilde{e}(\mathsf{u}_\varepsilon + \mathsf{u}_\mathrm{D}(t_\varepsilon)) : \tilde{e}(\mathsf{u}_\varepsilon + \mathsf{u}_\mathrm{D}(t_\varepsilon))\, \mathrm{d}x$$

$$\geq \int_{\Omega_1 \cup \Omega_2} \mathbb{C}^0 \tilde{e}(\mathsf{u} + \mathsf{u}_\mathrm{D}(t)) : \tilde{e}(\mathsf{u} + \mathsf{u}_\mathrm{D}(t))\, \mathrm{d}x,$$

which concludes the proof of (3.21a).

Concerning the mutual recovery sequence, we first of all observe that inequality (3.21b) is nontrivial only when the right hand side is finite. In particular this implies that $\check{\mathsf{u}} \in \mathcal{U}$, $\check{z} \in \mathcal{Z}$ and $z \geq \check{z} \geq 0$ on Γ_C. As done in [21], merging ideas from [7] and [61], we define

$$(\check{\mathsf{u}}_\varepsilon)_\alpha := \check{\mathsf{u}}_\alpha, \qquad \alpha = 1, 2, \tag{3.25a}$$

$$(\check{\mathsf{u}}_\varepsilon)_3 := \check{\mathsf{u}}_3 + \varepsilon^2 \eta_\varepsilon, \tag{3.25b}$$

$$\check{z}_\varepsilon := \begin{cases} z_\varepsilon \check{z}/z & \text{if } z > 0, \\ 0 & \text{if } z = 0, \end{cases} \tag{3.25c}$$

with $\eta_\varepsilon(x_1, x_2, x_3) := \int_0^{x_3} \psi_\varepsilon(x_1, x_2, s)\, \mathrm{d}s$ as $x_3 \in [-h_1, h_2]$ for some $\psi_\varepsilon \in C_0^\infty(\Omega)$ such that $\psi_\varepsilon \to \psi := -\sum_{\alpha,\beta=1}^2 \mathbb{C}_{33\alpha\beta} \tilde{e}(\check{\mathsf{u}} + \mathsf{u}_\mathrm{D}(t))_{\alpha\beta}/\mathbb{C}_{3333}$ and $\varepsilon \partial \psi_\varepsilon / \partial x_\alpha \to 0$ in $L^2(\Omega)$ for $\alpha = 1, 2$.

It is easy to check that with this choice we have that

$$\lim_{\varepsilon \to 0} \mathsf{R}_\varepsilon^d(\check{z}_\varepsilon - z_\varepsilon) = \mathsf{R}_0^d(\check{z} - z).$$

Thus, to prove the claim it suffices to deal with the convergence of the energy functional and the proof proceeds exactly as in [21, Lemma 4.5], with the only difference concerning the convergence of the term

$$\int_{\Gamma_\mathrm{C}} \check{z}_\varepsilon \mathsf{Q}^\varepsilon\big([\![\check{\mathsf{u}}_\varepsilon]\!]\big)\, \mathrm{d}\mathscr{H}^2$$

which we are going to discuss here. Under the non restrictive assumption $\mathsf{E}_{0,\kappa}(t, \check{\mathsf{u}}, \check{z}) < +\infty$, which implies

$$\check{z}[\![\check{\mathsf{u}}]\!]_\sigma = 0 \quad \text{if } q_\sigma < 0, \quad \sigma = \tau, \nu, \tag{3.26}$$

we have that the sequence

$$\int_{\Gamma_\mathrm{C}} \varepsilon^{q_\sigma} \check{z}_\varepsilon |[\![\check{\mathsf{u}}_\varepsilon]\!]_\sigma|^2\, \mathrm{d}\mathscr{H}^2 \begin{cases} \to \int_{\Gamma_\mathrm{C}} \check{z}|[\![\check{\mathsf{u}}]\!]_\sigma|^2\, \mathrm{d}\mathscr{H}^2 & \text{if } q_\sigma = 0, \text{ thanks to (3.22)}, \\ \to 0 & \text{if } q_\sigma > 0, \text{ thanks to (3.22)}, \\ = 0 & \text{if } q_\sigma < 0, \end{cases}$$

where the last line is because in that case $\check{z}_\varepsilon |[\![\check{\mathsf{u}}_\varepsilon]\!]_\sigma|^2 = \check{z}_\varepsilon |[\![\check{\mathsf{u}}]\!]_\sigma|^2 = 0$ by (3.26) and by definition of $\check{z}_\varepsilon$. Summarizing we have therefore

$$\int_{\Gamma_\mathrm{C}} \check{z}_\varepsilon \mathsf{Q}^\varepsilon\big([\![\check{\mathsf{u}}_\varepsilon]\!]\big)\, \mathrm{d}\mathscr{H}^2 \to \int_{\Gamma_\mathrm{C}} \check{z} \mathsf{Q}^0\big([\![\check{\mathsf{u}}]\!]\big)\, \mathrm{d}\mathscr{H}^2,$$

which concludes the proof. $\qquad \square$

Let us remark that the mutual recovery sequence condition stated in [50] is

$$\limsup_{\varepsilon \to 0} \left[\mathsf{E}_\varepsilon(t_\varepsilon, \breve{u}_\varepsilon, \breve{z}_\varepsilon) + \mathsf{R}^d_\varepsilon(\breve{z}_\varepsilon - z_\varepsilon) - \mathsf{E}_\varepsilon(t_\varepsilon, u_\varepsilon, z_\varepsilon) \right] \leq \mathsf{E}_0(t, \breve{u}, \breve{z}) + \mathsf{R}^d_0(\breve{z} - z) - \mathsf{E}_0(t, u, z)$$

where $(u_\varepsilon, z_\varepsilon)$ is a stable sequence converging to (u, z). This is, in general, slightly weaker than (3.21b), as proven in [50, Prop.2.2]. Anyhow, here proving right (3.21b) was even simpler.

The dimension reduction result is summarized in the next statement which can be proven by following the same lines of [21, Theorem 5.5].

Theorem 3.2 (Convergence for $\varepsilon \to 0$)**.** *Let* $q_0 = (u_0, z_0) \in \mathcal{Q}$ *and, for any* $\varepsilon > 0$, *let* $q_{0,\varepsilon} = (u_{0,\varepsilon}, z_{0,\varepsilon}) \in \mathcal{S}_\varepsilon(0)$ *with* $\mathcal{S}_\varepsilon$ *as in* (1.5) *with* E_ε *and* R^d_0 *in place of* $\mathcal{E}_\varepsilon$ *and* $\mathcal{R}_\varepsilon$, *and let* $q_{0,\varepsilon} \overset{*}{\rightharpoonup} q_0$ *and* $\mathsf{E}_\varepsilon(0, q_{0,\varepsilon}) \to \mathsf{E}_0(0, q_0)$ *as* $\varepsilon \to 0$. *Let further* $q_\varepsilon = (u_\varepsilon, z_\varepsilon) : [0, T] \to \mathcal{Q}$ *be an energetic solution to the problem* $(\mathcal{U} \times \mathcal{Z}, \mathsf{E}_\varepsilon, \mathsf{R}^d_\varepsilon, q_{0,\varepsilon})$. *Then, there exist* $q = (u, z) : [0, T] \to \mathcal{Q}$ *and a subsequence (indexed, for simplicity, again by* ε) *such that*

$$\mathsf{E}_\varepsilon(t, q_\varepsilon(t)) \to \mathsf{E}_0(t, q(t)) \qquad \text{for every } t \in [0, T], \tag{3.27a}$$

$$\mathsf{R}^d_\varepsilon(z_\varepsilon(t) - z_\varepsilon(0)) \to \mathsf{R}^d_0(z(t) - z(0)) \qquad \text{for every } t \in [0, T], \tag{3.27b}$$

$$\partial_t \mathsf{E}_\varepsilon(\cdot, q_\varepsilon(\cdot)) \to \partial_t \mathsf{E}_0(\cdot, q(\cdot)) \qquad \text{in } L^1(0, T), \tag{3.27c}$$

$$z_\varepsilon(t) \overset{*}{\rightharpoonup} z(t) \qquad \text{in } L^\infty(\Gamma_{\mathrm{C}}) \text{ for every } t \in [0, T], \tag{3.27d}$$

$$u_\varepsilon(t) \rightharpoonup u(t) \qquad \text{in } W^{1,2}(\Omega_1 \cup \Omega_2; \mathbb{R}^3) \text{ for every } t \in [0, T]. \tag{3.27e}$$

Moreover, any q *obtained in this way is an energetic solution to the problem* $(\mathcal{U} \times \mathcal{Z}, \mathsf{E}_0, \mathsf{R}^d_0, q_0)$.

The proof, as already mentioned, follows the same lines of [21, Theorem 5.5] and therefore is omitted. However, the reader can get an insight of this proof by looking at Section 5 where the proof of a more complicated case is provided.

Remark 3.3 (Isotropic material)**.** The most typical case of $\mathbb{C}$ is $\mathbb{C}_{ijkl} = \lambda \delta_{ij} \delta_{kl} + \mu(\delta_{ik} \delta_{jl} + \delta_{il} \delta_{jk})$ with $\mu > 0$ the so-called shear modulus, λ is the so-called bulk modulus, $\lambda + \frac{2}{3}\mu > 0$. Then the corresponding quadratic form becomes $\frac{1}{2}\mathbb{C}e{:}e = \mu|e|^2 + \frac{1}{2}\lambda|\mathrm{tr}\, e|^2$ and the quadratic form (3.14) determining $\mathbb{C}^0$ from (3.13) is $\frac{1}{2}\mathbb{C}^0\tilde{e}{:}\tilde{e} = 2\mu\tilde{e}_{12}^2 + \mu(\tilde{e}_{11}^2 + \tilde{e}_{22}^2) + \frac{\mu\lambda}{2\mu + \lambda}(\tilde{e}_{11} + \tilde{e}_{22})^2$, cf. [7].

Remark 3.4 (Scaling of the adhesive response)**.** The choice of the quadratic term Q^ε in (3.7) allows for an anisotropic behavior of the adhesive. In fact, the three-dimensional plate which is the starting point of our asymptotic analysis corresponds to the choice $\varepsilon = 1$. This means that the elastic response of the adhesive in the 3D model is characterized by the quadratic form

$$\mathsf{Q}^1(\llbracket u \rrbracket) := \kappa_\tau \left| \llbracket u \rrbracket_\tau \right|^2 + \kappa_\nu \left| \llbracket u \rrbracket_\nu \right|^2$$

and the case $\kappa_\tau = \kappa_\nu$ corresponds to an isotropic behavior of the adhesive. In the limit model, the response of the adhesive is described by the quadratic form Q^0 defined in (3.15). As already remarked, the choice $\kappa_\tau = \kappa_\nu = \kappa$ and $q_\tau = q_\nu = 0$ (which corresponds to an isotropic scaling) gives $\mathsf{Q}^0(\llbracket u \rrbracket) = \kappa|\llbracket u \rrbracket|^2$. If $q_\nu > 0$ and $q_\tau > 0$, the term involving Q^ε is so small that it simply disappears and thus the limit problem describes the *non-adhesive Signorini contact*. In particular, z will not evolve at all. The too-early-jump effect which energetic solutions may produce in non-convex problems trivially disappears in the limit. If instead $q_\nu < 0$ and $q_\tau < 0$ then the limit turns out to be a *brittle delamination* problem while, on the other hand, if $q_\nu = q_\tau = 0$ then the limit problem describes a kind of *adhesive contact*. In the remaining cases we end up with a mix of brittle delamination and adhesive or sliding (non-adhesive) contact problems. Generally speaking, the choice of the scaling of the various terms in the expression of Q^ε has, to some extent, a purely mathematical meaning: indeed, different scalings simply allow us to capture different properties of the solutions of the 3D problem, cf. [57]. Nevertheless, in our case this choice can also be driven by the physics of the problem, namely, by the kind of approximation that we decide to pursue and that we want to incorporate in the limit problem.

For constitutive reasons the elastic constants of the adhesive must satisfy the inequality $\kappa_\nu/\kappa_\tau \geq 2$, see Távara et al. [63]. If we know that κ_τ is much smaller with respect to κ_ν, then we can decide to "simplify" the problem with essentially three kinds of approximations. In the first, κ_τ is so small that we choose to approximate the behavior of the adhesive with a Signorini contact problem in the plane and by an adhesive contact in the normal direction: this corresponds to the choice $q_\tau > 0$ and $q_\nu = 0$. In the second, κ_ν is so large that we choose the approximation with a brittle delamination problem in the normal direction and an adhesive contact in the plane: this corresponds to $q_\tau = 0$ and $q_\nu < 0$. In the third, κ_τ is so small and κ_ν so large that we choose to approximate with a Signorini contact in the plane and a brittle delamination in the normal: this corresponds to $q_\tau > 0$ and $q_\nu < 0$. Finally, we could instead take $q_\tau = q_\nu = 0$ and obtain an adhesive problem with constants κ_τ and κ_ν also in the limit problem, without any approximation.

4   Delaminating Kirchhoff-Love plate reformulated on Γ_{C}

The aim of this section is to provide a truly two-dimensional formulation of the limit problem merely on Γ_{C}.

Let us recall that $\mathsf{u} \in W^{1,2}_{\mathrm{KL}}(\Omega_1 \cup \Omega_2; \mathbb{R}^3)$ if and only if there exist $\rho^\ell = (\rho^\ell_1, \rho^\ell_2) \in W^{1,2}(\Gamma_{\mathrm{C}}; \mathbb{R}^2)$ and $\xi^\ell \in W^{2,2}(\Gamma_{\mathrm{C}})$ such that

$$\mathsf{u}_\alpha(x_1, x_2, x_3) = \begin{cases} \rho^1_\alpha(x_1, x_2) - x_3 \frac{\partial}{\partial x_\alpha} \xi^1(x_1, x_2) & \text{if } x_3 \in (-h_1/2, 0), \\ \rho^2_\alpha(x_1, x_2) - x_3 \frac{\partial}{\partial x_\alpha} \xi^2(x_1, x_2) & \text{if } x_3 \in (0, h_2/2), \end{cases} \quad \text{with } \alpha = 1, 2, \qquad (4.1a)$$

$$\mathsf{u}_3(x_1, x_2, x_3) = \begin{cases} \xi^1(x_1, x_2) & \text{if } x_3 \in (-h_1/2, 0), \\ \xi^2(x_1, x_2) & \text{if } x_3 \in (0, h_2/2), \end{cases} \quad \text{for } (x_1, x_2) \in \Gamma_{\mathrm{C}}, \qquad (4.1b)$$

see Le Dret [38, Lemma 4.2] for the case of a single plate. Since the effective domain of the limit energy $\mathsf{E}_{0,\kappa}$ is contained in the set of Kirchhoff-Love displacements $W^{1,2}_{\mathrm{KL}}(\Omega_1 \cup \Omega_2; \mathbb{R}^3)$ (see (3.17)), it is thus possible to rewrite the limit energy functionals in terms of the Kirchhoff-Love generalized displacements ρ^ℓ and ξ^ℓ, with $\ell = 1, 2$.

Recalling the expression (3.4) of u_{D}, we first observe that

$$\tilde{e}(\mathsf{u}) = \begin{cases} \tilde{e}(\rho^1) - x_3 \nabla^2 \xi^1 & \text{if } x_3 \in (-h_1/2, 0), \\ \tilde{e}(\rho^2) - x_3 \nabla^2 \xi^2 & \text{if } x_3 \in (0, h_2/2), \end{cases} \quad \text{and} \quad \tilde{e}(\mathsf{u}_{\mathrm{D}}) = \tilde{e}(\rho_{\mathrm{D}}) - x_3 \nabla^2 \xi_{\mathrm{D}}$$

for some ρ_{D} and ξ_{D} given. In terms of these new variables, we have

$$\frac{1}{2} \int_{\Omega_1 \cup \Omega_2} \mathbb{C}^0 \tilde{e}(\mathsf{u} + \mathsf{u}_{\mathrm{D}}) : \tilde{e}(\mathsf{u} + \mathsf{u}_{\mathrm{D}}) \, \mathrm{d}x = \frac{1}{2} \sum_{\ell=1,2} \int_{\Gamma_{\mathrm{C}}} \frac{h_\ell}{2} \mathbb{C}^0 \tilde{e}(\rho^\ell + \rho_{\mathrm{D}}) : \tilde{e}(\rho^\ell + \rho_{\mathrm{D}}) +$$

$$+ (-1)^{\ell+1} \frac{h_\ell^2}{8} \mathbb{C}^0 \tilde{e}(\rho^\ell + \rho_{\mathrm{D}}) : \nabla^2(\xi^\ell + \xi_{\mathrm{D}}) + \frac{h_\ell^3}{24} \mathbb{C}^0 \nabla^2(\xi^\ell + \xi_{\mathrm{D}}) : \nabla^2(\xi^\ell + \xi_{\mathrm{D}}) \, \mathrm{d}\mathscr{H}^2$$

while

$$\int_{\Omega_1 \cup \Omega_2} \mathsf{f} \cdot (\mathsf{u} + \mathsf{u}_{\mathrm{D}}) \, \mathrm{d}x = \sum_{\ell=1,2} \int_{\Gamma_{\mathrm{C}}} \varphi^0_3(\xi^\ell + \xi_{\mathrm{D}}) + \sum_{\alpha=1,2} \varphi^0_\alpha(\rho^\ell_\alpha + [\rho_{\mathrm{D}}]_\alpha) - \varphi^1_\alpha \frac{\partial}{\partial x_\alpha}(\xi^\ell + \xi_{\mathrm{D}}) \, \mathrm{d}\mathscr{H}^2$$

$$\text{with} \quad \varphi^s_\alpha(x_1, x_2) := 1_0(\ell_\tau) \int_{-h_1/2}^{h_2/2} x_3^s \mathsf{f}_\alpha(x_1, x_2, x_3) \, \mathrm{d}x_3, \qquad (x_1, x_2) \in \Gamma_{\mathrm{C}},$$

$$\varphi^s_3(x_1, x_2) := 1_0(\ell_\nu) \int_{-h_1/2}^{h_2/2} x_3^s \mathsf{f}_3(x_1, x_2, x_3) \, \mathrm{d}x_3, \qquad (x_1, x_2) \in \Gamma_{\mathrm{C}},$$

where, for simplicity, we have not stressed the dependence of u_{D}, f, ρ_{D}, ξ_{D}, and φ^s_i on t. Since

$$\left| [\![\mathsf{u}]\!]_\tau \right|^2 = \sum_{\alpha=1}^2 \left| [\![\mathsf{u}_\alpha]\!] \right|^2 = \sum_{\alpha=1}^2 \left| \rho^1_\alpha - \rho^2_\alpha \right|^2 = |\rho^1 - \rho^2|^2, \qquad \left| [\![\mathsf{u}]\!]_\nu \right|^2 = \left| [\![\mathsf{u}_3]\!] \right|^2 = \left| \xi^1 - \xi^2 \right|^2$$

12

we have that, according to (3.15),

$$Q^0([\![u]\!]) = 1_0(q_\tau)\kappa_\tau|\rho^1-\rho^2|^2 + 1_0(q_\nu)\kappa_\nu|\xi^1-\xi^2|^2. \tag{4.2}$$

In terms of the new variables, the set $\mathsf{A}_{\mathrm{KL}}^{\mathrm{ad}}$ becomes

$$\begin{aligned}
\widehat{\mathsf{A}}_{\mathrm{KL}}^{\mathrm{ad}} := \Big\{ &(\rho,\xi,z) \in W^{1,2}(\Gamma_{\mathrm{C}};\mathbb{R}^2)^2 \times W^{2,2}(\Gamma_{\mathrm{C}})^2 \times L^\infty(\Gamma_{\mathrm{C}}) : 0 \le z \le 1,\ \xi^1 \ge \xi^2 \text{ a.e. on } \Gamma_{\mathrm{C}}, \\
&z|\rho^1 - \rho^2| = 0 \text{ if } q_\tau < 0,\ z(\xi^1 - \xi^2) = 0 \text{ if } q_\nu < 0, \\
&\rho^\ell|_{\gamma_{\mathrm{D}\ell}} = 0,\ \ \xi^\ell|_{\gamma_{\mathrm{D}\ell}} = \nabla\xi^\ell|_{\gamma_{\mathrm{D}\ell}}\cdot\nu = 0 \text{ a.e. on } \gamma_{\mathrm{D}\ell},\ \ \ell = 1,2 \Big\},
\end{aligned} \tag{4.3}$$

and the stored energy is

$$\widehat{\mathsf{E}}_0(t,\rho,\xi,z) := \begin{cases}
\dfrac{1}{2}\displaystyle\int_{\Gamma_{\mathrm{C}}} \sum_{\ell=1,2} \Big(\dfrac{h_\ell}{2}\mathbb{C}^0\tilde{e}(\rho^\ell+\rho_{\mathrm{D}}){:}\tilde{e}(\rho^\ell+\rho_{\mathrm{D}}) + (-1)^{\ell+1}\dfrac{h_\ell^2}{8}\mathbb{C}^0\tilde{e}(\rho^\ell+\rho_{\mathrm{D}}){:}\nabla^2(\xi^\ell+\xi_{\mathrm{D}}) \\
\qquad + \dfrac{h_\ell^3}{24}\mathbb{C}^0\nabla^2(\xi^\ell+\xi_{\mathrm{D}}){:}\nabla^2(\xi^\ell+\xi_{\mathrm{D}}) - \varphi_3^0(\xi^\ell+\xi_{\mathrm{D}}) - \varphi_\alpha^0(\rho_\alpha^\ell+[\rho_{\mathrm{D}}]_\alpha) + \varphi_\alpha^1\dfrac{\partial}{\partial x_\alpha}(\xi^\ell+\xi_{\mathrm{D}}) \Big) \\
\qquad + z1_0(q_\tau)\kappa_\tau|\rho^1-\rho^2|^2 + z1_0(q_\nu)\kappa_\nu|\xi^1-\xi^2|^2 \,\mathrm{d}\mathscr{H}^2 \qquad\qquad \text{if } (\rho,\xi,z) \in \widehat{\mathsf{A}}_{\mathrm{KL}}^{\mathrm{ad}}, \\[2mm]
+\infty \qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\quad \text{else.}
\end{cases}$$

Moreover, we consider the dissipation R_0^d from (3.19). The limit problem admits therefore a purely 2D formulation, thanks to (4.1).

5 Mode-sensitive delamination

Engineering models of delamination are usually more complicated than presented here so far: the dissipation in the so-called mode I (delamination by opening) is less than in the so-called mode II (delamination by shearing); sometimes, the difference may be tens or even hundreds of percents, cf., e.g., [42, 45]. Recently, a quasistatic associative model has been devised, analyzed, and tested computationally in [59,60]. The purpose of this last section is to adapt the previously exposed asymptotic analysis to this mode-sensitive model.

5.1 Formulation of the problem and scaling

Microscopically, the additional dissipation in Mode II may be explained by a certain plastic process both in the adhesive itself and in a narrow bulk vicinity of the delamination surface before the actual delamination starts, cf. [42, 64]. Following [59, 60], we are therefore led to consider an additional plastic-like inelastic process on Γ_{C} described by a further dissipative variable π having the meaning of the "plastic" interfacial slip on Γ_{C}. Denoting the delamination parameter by ζ in this section, the "rate-independent variable" z then will have two components, i.e., $z = (\zeta,\pi)$.

Instead of $\widetilde{\mathcal{E}}_\varepsilon$ and $\mathcal{R}_\varepsilon$ from (2.1) and (2.3), we now consider the following energy functionals proposed in [59,60]

$$\widetilde{\mathcal{E}}_\varepsilon(t,u,\zeta,\pi) = \begin{cases}
\dfrac{1}{2}\displaystyle\int_{\Omega_1^\varepsilon\cup\Omega_2^\varepsilon} \mathbb{C}e(u){:}e(u) - 2f^\varepsilon(t)\cdot u \,\mathrm{d}x \\
\qquad + \displaystyle\int_{\Gamma_{\mathrm{C}}} \zeta Q^\varepsilon([\![u]\!]-\mathbb{T}\pi) + \dfrac{\kappa_{\mathrm{H}}^\varepsilon}{2}|\pi|^2 + \dfrac{\kappa_0^\varepsilon}{2}|\nabla_{\mathrm{s}}\pi|^2 \,\mathrm{d}\mathscr{H}^2 & \text{if } (u,\zeta) \in \mathcal{A}_\varepsilon^{\mathrm{ad}}(w_{\mathrm{D}}^\varepsilon(t)), \\
& \text{and } \pi \in W^{1,2}(\Gamma_{\mathrm{C}};\mathbb{R}^2), \\[2mm]
+\infty & \text{else,}
\end{cases} \tag{5.1a}$$

13

where ∇_{s} is the gradient along the two-dimensional surface Γ_{C} and $\mathbb{T} : \mathbb{R}^2 \to \mathbb{R}^3 : (\pi_1, \pi_2) \mapsto (\pi_1, \pi_2, 0)$, and

$$\mathcal{R}_\varepsilon\big(\dot\zeta, \dot\pi\big) := \begin{cases} \displaystyle\int_{\Gamma_{\mathrm{C}}} a_\varepsilon |\dot\zeta| + \sigma_{\varepsilon,\mathrm{yield}} |\dot\pi| \, \mathrm{d}\mathscr{H}^2 & \text{if } \dot\zeta \leq 0 \text{ on } \Gamma_{\mathrm{C}}, \\ +\infty & \text{else.} \end{cases} \tag{5.1b}$$

Instead of $\mathcal{Z}$ from (2.10), $z = (\zeta, \pi)$ lives in the space

$$\mathcal{Z} := \big\{ (\zeta, \pi) \in L^\infty(\Gamma_{\mathrm{C}}) \times W^{1,2}(\Gamma_{\mathrm{C}}; \mathbb{R}^2); \ 0 \leq \zeta \leq 1 \ \text{ on } \Gamma_{\mathrm{C}} \big\}.$$

The coefficient $\kappa_{\mathrm{H}}^\varepsilon > 0$ is related with a kinematic-type hardening. The idea of this model is that under increasing load, in Mode II, first the interfacial slip starts evolving when the stress achieves the threshold $\sigma_{\varepsilon,\mathrm{yield}}$ and, due to the hardening, the stress still continues growing until the threshold a_ε activates the delamination ζ which then eventually stops also the evolution of π. This implies that the driving stress for π has, after delamination, a magnitude less than $\sigma_{\varepsilon,\mathrm{yield}}$. This scenario needs the condition

$$\frac{1}{2} \kappa_\tau^\varepsilon a_\varepsilon < \sigma_{\varepsilon,\mathrm{yield}}^2 \leq 2 \kappa_\tau^\varepsilon a_\varepsilon \qquad \text{with} \quad \kappa_\tau^\varepsilon = [Q^\varepsilon]_\tau'' \tag{5.2}$$

to be satisfied, cf. [59, Formula (13.69)] or [60, Formula (14)], where $[Q^\varepsilon]_\tau''$ here denotes the second tangential derivative of Q^ε. The validity of this model has been tested numerically in [60]. Dealing now for simplicity with the case $q_\tau = q_\nu = 0$ in the definition (3.6) of Q^ε, from the relation above we obtain that

$$\kappa_\tau^\varepsilon = 2\varepsilon k_\tau.$$

Taking into account that $a_\varepsilon = \varepsilon^3 \mathsf{a}$, cf. (3.10), the two-sided condition (5.2) turns into $\varepsilon^4 k_\tau \mathsf{a} \leq \sigma_{\varepsilon,\mathrm{yield}}^2 \leq 4\varepsilon^4 k_\tau \mathsf{a}$. It leads us to set

$$\sigma_{\varepsilon,\mathrm{yield}} = \varepsilon^2 \sigma_{\mathrm{yield}} \tag{5.3}$$

for some σ_{yield} satisfying

$$k_\tau \mathsf{a} < \sigma_{\mathrm{yield}}^2 \leq 4 k_\tau \mathsf{a}. \tag{5.4}$$

The energy dissipated in Mode II, let us denote it by $a_\varepsilon^{\mathrm{II}}$, is

$$a_\varepsilon^{\mathrm{II}} = a_\varepsilon + \frac{\sigma_{\varepsilon,\mathrm{yield}} \sqrt{2\kappa_{\mathrm{t}}^\varepsilon a_\varepsilon} - \sigma_{\varepsilon,\mathrm{yield}}^2}{\kappa_{\mathrm{H}}^\varepsilon}, \tag{5.5}$$

cf. again [59,60], and then the so-called fracture-mode sensitivity $a_\varepsilon^{\mathrm{II}}/a_\varepsilon$ is indeed bigger than 1 as expected in engineering models, namely

$$\frac{a_\varepsilon^{\mathrm{II}}}{a_\varepsilon} = 1 + \frac{\sigma_{\varepsilon,\mathrm{yield}}}{\kappa_{\mathrm{H}}^\varepsilon} \sqrt{\frac{2\kappa_{\mathrm{t}}^\varepsilon}{a_\varepsilon}} - \frac{\sigma_{\varepsilon,\mathrm{yield}}^2}{\kappa_{\mathrm{H}}^\varepsilon a_\varepsilon}. \tag{5.6}$$

Setting

$$\kappa_{\mathrm{H}}^\varepsilon = \varepsilon \kappa_{\mathrm{H}}, \quad \kappa_{\mathrm{H}} > 0,$$

we can control $a_\varepsilon^{\mathrm{II}}/a_\varepsilon$ uniformly with respect to ε.

Let us remark that, to fit it more straightforwardly to the previous sections, we used the model with $\nabla_{\mathrm{s}} \pi$, as suggested in [60, Remark 3]. Then this model is indeed an extension of the previous model in the sense that, if $\sigma_{\mathrm{yield}} > 4 k_\tau \mathsf{a}$ and $\pi(0) = 0$, no plastic slip is ever triggered and this model gives the same response as that one in Section 2.

14

Following the same lines traced at the end of Section 2, instead of (5.1a), we can consider

$$
\mathcal{E}_\varepsilon(t, \mathsf{u}, \zeta, \pi) = \begin{cases} \dfrac{1}{2} \displaystyle\int_{\Omega_1^\varepsilon \cup \Omega_2^\varepsilon} \mathbb{C}e(u + u_D^\varepsilon(t)){:}e(u + u_D^\varepsilon(t)) - 2f^\varepsilon(t){\cdot}(u + u_D^\varepsilon(t)) \, \mathrm{d}x \\[2mm] \qquad + \displaystyle\int_{\Gamma_\mathrm{C}} \zeta Q^\varepsilon\big(\llbracket u \rrbracket - \mathbb{T}\pi\big) + \dfrac{\kappa_\mathrm{H}^\varepsilon}{2}|\pi|^2 + \dfrac{\kappa_0^\varepsilon}{2}\big|\nabla_\mathrm{s}\pi\big|^2 \, \mathrm{d}\mathscr{H}^2 \qquad \text{if } (u, \zeta) \in \mathcal{A}_\varepsilon^{\mathrm{ad}}, \\[2mm] \qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad \text{and } \boldsymbol{\pi} \in W^{1,2}(\Gamma_\mathrm{C}, \mathbb{R}^2), \\[3mm] +\infty \qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad \text{else.} \end{cases}
$$

Scaling displacements and body forces and choosing Dirichlet boundary conditions as at the beginning of Section 3.1, we introduce the scaled interfacial slip

$$
\boldsymbol{\pi} := \frac{1}{\varepsilon}\pi \circ p_\varepsilon
$$

and set

$$
\kappa_0^\varepsilon = \varepsilon\kappa_0, \quad \kappa_0 > 0,
$$

in order to obtain

$$
\mathcal{E}_\varepsilon(t, u, \zeta, \pi) = \varepsilon^3 \mathsf{E}_\varepsilon(t, \mathsf{u}, \zeta, \boldsymbol{\pi}),
$$

for $(u, \zeta) \in \mathcal{A}_\varepsilon^{\mathrm{ad}}$, where

$$
\mathsf{E}_\varepsilon(t, \mathsf{u}, \zeta, \boldsymbol{\pi}) = \begin{cases} \dfrac{1}{2} \displaystyle\int_{\Omega_1 \cup \Omega_2} \mathbb{C}e^\varepsilon(\mathsf{u} + \mathsf{u}_\mathrm{D}(t)){:}e^\varepsilon(\mathsf{u} + \mathsf{u}_\mathrm{D}(t)) - 2\mathsf{f}^\varepsilon(t){\cdot}(\mathsf{u} + \mathsf{u}_\mathrm{D}(t)) \, \mathrm{d}x \\[2mm] \qquad + \displaystyle\int_{\Gamma_\mathrm{C}} \zeta Q^\varepsilon\big(\llbracket \mathsf{u} \rrbracket - \mathbb{T}\boldsymbol{\pi}\big) + \dfrac{\kappa_\mathrm{H}}{2}|\boldsymbol{\pi}|^2 + \dfrac{\kappa_0}{2}\big|\nabla_\mathrm{s}\boldsymbol{\pi}\big|^2 \, \mathrm{d}\mathscr{H}^2 \quad \text{if } (\mathsf{u}, \zeta) \in \mathsf{A}^{\mathrm{ad}} \\[2mm] \qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\quad \text{and } \boldsymbol{\pi} \in W^{1,2}(\Gamma_\mathrm{C}, \mathbb{R}^2), \\[3mm] +\infty \qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\quad \text{else.} \end{cases} \tag{5.7}
$$

Concerning the dissipation energy, contrarily to what we have done in Section 3, we consider here only the scaling that leads to a non trivial limit dissipation; namely, under the scalings (3.10) with $d = 0$ and (5.3), we have

$$
\mathcal{R}_\varepsilon(\dot{\zeta}, \dot{\pi}) = \varepsilon^3 \mathsf{R}(\dot{\zeta}, \dot{\boldsymbol{\pi}}),
$$

where

$$
\mathsf{R}(\dot{\zeta}, \dot{\boldsymbol{\pi}}) := \begin{cases} \displaystyle\int_{\Gamma_\mathrm{C}} \mathsf{a}|\dot{\zeta}| + \sigma_{\mathrm{yield}}|\dot{\boldsymbol{\pi}}| \, \mathrm{d}\mathscr{H}^2 & \text{if } \dot{\zeta} \leq 0 \text{ on } \Gamma_\mathrm{C}, \\[2mm] +\infty & \text{else.} \end{cases}
$$

Then we define

$$
\mathsf{E}_0(t, \zeta, \mathsf{u}, \boldsymbol{\pi}) = \begin{cases} \dfrac{1}{2} \displaystyle\int_{\Omega_1 \cup \Omega_2} \mathbb{C}^0\tilde{e}(\mathsf{u} + \mathsf{u}_\mathrm{D}(t)){:}\tilde{e}(\mathsf{u} + \mathsf{u}_\mathrm{D}(t)) - 2\mathsf{f}^0(t){\cdot}(\mathsf{u} + \mathsf{u}_\mathrm{D}(t)) \, \mathrm{d}x \\[2mm] \qquad + \displaystyle\int_{\Gamma_\mathrm{C}} \zeta Q^0\big(\llbracket \mathsf{u} \rrbracket - \mathbb{T}\boldsymbol{\pi}\big) + \dfrac{\kappa_\mathrm{H}}{2}|\boldsymbol{\pi}|^2 + \dfrac{\kappa_0}{2}\big|\nabla_\mathrm{s}\boldsymbol{\pi}\big|^2 \, \mathrm{d}\mathscr{H}^2 \quad \text{if } (\mathsf{u}, \zeta) \in \mathsf{A}_{\mathrm{KL}}^{\mathrm{ad}}, \\[2mm] \qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\quad \text{and } \boldsymbol{\pi} \in W^{1,2}(\Gamma_\mathrm{C}, \mathbb{R}^2), \\[3mm] +\infty \qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\quad \text{else,} \end{cases} \tag{5.8}
$$

where now

$$
\mathsf{A}_{\mathrm{KL}}^{\mathrm{ad}} = \big\{ (\mathsf{u}, \zeta) \in \mathsf{A}^{\mathrm{ad}} \ : \ \mathsf{u} \in W_{\mathrm{KL}}^{1,2}(\Omega_1 \cup \Omega_2; \mathbb{R}^3) \big\}.
$$

5.2 Dimension reduction

Now we are going to perform the same analysis (dimension reduction and relation between energetic solutions associated to the rescaled and the limit problems) that we discussed in Section 3, providing in particular the link between the functionals E_ε and E_0. Again, the main idea is to apply the abstract scheme developed in [50]. This case involving mixed modes of delamination is more complicated and requires much detailed adaptations. Also for the sake of clarity, we preferred to give the whole proofs.

In the next lemma we prove a lower bound for the limit energies.

Lemma 5.1 (Lower semicontinuity). *If* $t_\varepsilon \to t$, $\zeta_\varepsilon \overset{*}{\rightharpoonup} \zeta$ *in* $L^\infty(\Gamma_{\mathrm{C}})$, $0 \le \zeta_\varepsilon \le 1$ *a.e.*, $\boldsymbol{\pi}_\varepsilon \rightharpoonup \boldsymbol{\pi}$ *in* $W^{1,2}(\Gamma_{\mathrm{C}};\mathbb{R}^2)$ *and* $\mathsf{u}_\varepsilon \rightharpoonup \mathsf{u}$ *in* $W^{1,2}(\Omega_1 \cup \Omega_2;\mathbb{R}^3)$ *as* $\varepsilon \to 0^+$, *then*

$$\liminf_{\varepsilon \to 0^+} \mathsf{E}_\varepsilon(t_\varepsilon, \mathsf{u}_\varepsilon, \zeta_\varepsilon, \boldsymbol{\pi}_\varepsilon) \ge \mathsf{E}_0(t, \mathsf{u}, \zeta, \boldsymbol{\pi}). \tag{5.9}$$

Proof. Under the assumption that the liminf on the left-hand sides be finite, by the positive definiteness of $\mathbb{C}$ (see (2.4)) and the continuity of w with respect to t, it follows that, up to subsequences, $\left\| e^\varepsilon(\mathsf{u}_\varepsilon) \right\|_{L^2} \le C$ and hence $\left\| e(\mathsf{u}_\varepsilon)_{i3} \right\|_{L^2} \le C\varepsilon$, $i = 1, 2, 3$; thus, passing to the limit, we obtain $e(\mathsf{u})_{i3} = 0$ which implies $\mathsf{u} \in W^{1,2}_{\mathrm{KL}}(\Omega_1 \cup \Omega_2;\mathbb{R}^3)$. By this fact and by Lemma 3.1 we have that also the right-hand side in (5.9) is finite and that it suffices to prove that

$$\liminf_{\varepsilon \to 0^+} \int_{\Omega_1 \cup \Omega_2} \mathbb{C}e^\varepsilon(\mathsf{u}_\varepsilon + \mathsf{w}(t_\varepsilon)){:}e^\varepsilon(\mathsf{u}_\varepsilon + \mathsf{w}(t_\varepsilon)) \, \mathrm{d}x + \int_{\Gamma_{\mathrm{C}}} \zeta_\varepsilon \mathsf{Q}^\varepsilon\left(\llbracket \mathsf{u}_\varepsilon \rrbracket - \mathbb{T}\boldsymbol{\pi}_\varepsilon\right) + \frac{\kappa_{\mathrm{H}}}{2}|\boldsymbol{\pi}_\varepsilon|^2 + \frac{\kappa_0}{2}\left|\nabla_{\mathrm{s}}\boldsymbol{\pi}_\varepsilon\right|^2 \mathrm{d}\mathcal{H}^2 \ge$$

$$\ge \int_{\Omega_1 \cup \Omega_2} \mathbb{C}^0 \tilde{e}(\mathsf{u} + \mathsf{w}(t)){:}\tilde{e}(\mathsf{u} + \mathsf{w}(t)) \, \mathrm{d}x + \int_{\Gamma_{\mathrm{C}}} \zeta \mathsf{Q}^0\left(\llbracket \mathsf{u} \rrbracket - \mathbb{T}\boldsymbol{\pi}\right) + \frac{\kappa_{\mathrm{H}}}{2}|\boldsymbol{\pi}|^2 + \frac{\kappa_0}{2}\left|\nabla_{\mathrm{s}}\boldsymbol{\pi}\right|^2 \mathrm{d}\mathcal{H}^2.$$

The bulk term can be treated as we did in the proof of (3.21a) noticing that, for $\alpha, \beta = 1, 2$,

$$e^\varepsilon(\mathsf{u}_\varepsilon)_{\alpha\beta} = e(\mathsf{u}_\varepsilon)_{\alpha\beta} \rightharpoonup e(\mathsf{u})_{\alpha\beta} \quad \text{in } L^2(\Omega_1 \cup \Omega_2),$$

using property (3.14) and the continuity of w with respect to t to obtain

$$\liminf_{\varepsilon \to 0^+} \int_{\Omega_1 \cup \Omega_2} \mathbb{C}e^\varepsilon(\mathsf{u}_\varepsilon + \mathsf{w}(t_\varepsilon)){:}e^\varepsilon(\mathsf{u}_\varepsilon + \mathsf{w}(t_\varepsilon)) \, \mathrm{d}x \ge \liminf_{\varepsilon \to 0^+} \int_{\Omega_1 \cup \Omega_2} \mathbb{C}^0 \tilde{e}(\mathsf{u}_\varepsilon + \mathsf{w}(t_\varepsilon)){:}\tilde{e}(\mathsf{u}_\varepsilon + \mathsf{w}(t_\varepsilon)) \, \mathrm{d}x$$

$$\ge \int_{\Omega_1 \cup \Omega_2} \mathbb{C}^0 \tilde{e}(\mathsf{u} + \mathsf{w}(t)){:}\tilde{e}(\mathsf{u} + \mathsf{w}(t)) \, \mathrm{d}x.$$

Since $\boldsymbol{\pi}_\varepsilon \rightharpoonup \boldsymbol{\pi}$ in $W^{1,2}(\Gamma_{\mathrm{C}};\mathbb{R}^2)$ then we immediately get

$$\liminf_{\varepsilon \to 0^+} \int_{\Gamma_{\mathrm{C}}} \frac{\kappa_{\mathrm{H}}}{2}|\boldsymbol{\pi}_\varepsilon|^2 + \frac{\kappa_0}{2}\left|\nabla_{\mathrm{s}}\boldsymbol{\pi}_\varepsilon\right|^2 \mathrm{d}\mathcal{H}^2 \ge \int_{\Gamma_{\mathrm{C}}} \frac{\kappa_{\mathrm{H}}}{2}|\boldsymbol{\pi}|^2 + \frac{\kappa_0}{2}\left|\nabla_{\mathrm{s}}\boldsymbol{\pi}\right|^2 \mathrm{d}\mathcal{H}^2.$$

Finally, concerning the term involving Q^ε we have

$$\lim_{\varepsilon \to 0^+} \int_{\Gamma_{\mathrm{C}}} \zeta_\varepsilon \mathsf{Q}^\varepsilon\left(\llbracket \mathsf{u}_\varepsilon \rrbracket - \mathbb{T}\boldsymbol{\pi}_\varepsilon\right) \mathrm{d}\mathcal{H}^2 = \lim_{\varepsilon \to 0^+} \int_{\Gamma_{\mathrm{C}}} \zeta_\varepsilon\left(\kappa_\tau|\llbracket \mathsf{u}_\varepsilon \rrbracket_\tau - \boldsymbol{\pi}_\varepsilon|^2 + \kappa_\nu|\llbracket \mathsf{u}_\varepsilon \rrbracket_\nu|^2\right) \mathrm{d}\mathcal{H}^2$$

$$= \int_{\Gamma_{\mathrm{C}}} \zeta\left(\kappa_\tau|\llbracket \mathsf{u} \rrbracket_\tau - \boldsymbol{\pi}|^2 + \kappa_\nu|\llbracket \mathsf{u} \rrbracket_\nu|^2\right) \mathrm{d}\mathcal{H}^2 \tag{5.10}$$

$$= \int_{\Gamma_{\mathrm{C}}} \zeta \mathsf{Q}^0\left(\llbracket \mathsf{u} \rrbracket - \mathbb{T}\boldsymbol{\pi}\right) \mathrm{d}\mathcal{H}^2,$$

where in the first and last equalities we used the definitions of Q^ε and Q^0 respectively, while the second follows by observing that, by our assumptions,

$$\kappa_\tau|\llbracket \mathsf{u}_\varepsilon \rrbracket_\tau - \boldsymbol{\pi}_\varepsilon|^2 + \kappa_\nu|\llbracket \mathsf{u}_\varepsilon \rrbracket_\nu|^2 \to \kappa_\tau|\llbracket \mathsf{u} \rrbracket_\tau - \boldsymbol{\pi}|^2 + \kappa_\nu|\llbracket \mathsf{u} \rrbracket_\nu|^2 \text{ in } L^1(\Gamma_{\mathrm{C}}),$$

while $\zeta_\varepsilon \overset{*}{\rightharpoonup} \zeta$ in $L^\infty(\Gamma_{\mathrm{C}})$. $\qquad\square$

The next lemma is fundamental to apply the Γ-convergence scheme developed in [50].

Lemma 5.2 (Mutual recovery sequence)**.** *Let* $t \in [0, T]$*, and* $(\mathsf{u}, (\zeta, \boldsymbol{\pi}))) \in \mathcal{U} \times \mathcal{Z}$*. For every uniformly stable sequence* $(t_\varepsilon, \mathsf{u}_\varepsilon, (\zeta_\varepsilon, \boldsymbol{\pi}_\varepsilon)) \in [0, T] \times \mathcal{U} \times \mathcal{Z}$ *such that* $t_\varepsilon \to t$ *in* $[0, T]$*,* $\mathsf{u}_\varepsilon \rightharpoonup \mathsf{u}$ *in* $W^{1,2}(\Omega_1 \cup \Omega_2; \mathbb{R}^3)$*,* $\zeta_\varepsilon \overset{*}{\rightharpoonup} \zeta$ *in* $L^\infty(\Gamma_{\mathrm{C}})$*,* $\boldsymbol{\pi}_\varepsilon \rightharpoonup \boldsymbol{\pi}$ *in* $W^{1,2}(\Gamma_{\mathrm{C}}; \mathbb{R}^2)$*, and for every* $(\check{\mathsf{u}}, (\check{\zeta}, \check{\boldsymbol{\pi}})) \in \mathcal{U} \times \mathcal{Z}$*, there exist* $\check{\mathsf{u}}_\varepsilon \in \mathcal{U}$ *and* $(\check{\zeta}_\varepsilon, \check{\boldsymbol{\pi}}_\varepsilon) \in \mathcal{Z}$ *such that*

$$\check{\mathsf{u}}_\varepsilon \rightharpoonup \check{\mathsf{u}} \text{ in } W^{1,2}(\Omega_1 \cup \Omega_2; \mathbb{R}^3), \tag{5.11}$$

$$\check{\zeta}_\varepsilon \overset{*}{\rightharpoonup} \check{\zeta} \text{ in } L^\infty(\Gamma_{\mathrm{C}}), \tag{5.12}$$

$$\check{\boldsymbol{\pi}}_\varepsilon \rightharpoonup \check{\boldsymbol{\pi}} \text{ in } W^{1,2}(\Gamma_{\mathrm{C}}; \mathbb{R}^2), \tag{5.13}$$

$$\limsup_{\varepsilon \to 0^+} \left[\mathsf{E}_\varepsilon(t_\varepsilon, \check{\mathsf{u}}_\varepsilon, \check{\zeta}_\varepsilon, \check{\boldsymbol{\pi}}_\varepsilon) + \mathsf{R}(\check{\zeta}_\varepsilon - \zeta_\varepsilon, \check{\boldsymbol{\pi}}_\varepsilon - \boldsymbol{\pi}_\varepsilon) - \mathsf{E}_\varepsilon(t_\varepsilon, \mathsf{u}_\varepsilon, \zeta_\varepsilon, \boldsymbol{\pi}_\varepsilon) \right]$$

$$\leq \mathsf{E}_0(t, \check{\mathsf{u}}, \check{\zeta}, \check{\boldsymbol{\pi}}) + \mathsf{R}(\check{\zeta} - \zeta, \check{\boldsymbol{\pi}} - \boldsymbol{\pi}) - \mathsf{E}_0(t, \mathsf{u}, \zeta, \boldsymbol{\pi}). \tag{5.14}$$

Moreover, setting for any $\varepsilon \geq 0$

$$\bar{\mathsf{E}}_\varepsilon(t, \mathsf{u}, \zeta, \boldsymbol{\pi}) := \mathsf{E}_\varepsilon(t, \mathsf{u}, \zeta, \boldsymbol{\pi}) - \int_{\Gamma_{\mathrm{C}}} \frac{\kappa_0}{2} |\nabla_{\mathrm{s}} \boldsymbol{\pi}|^2 \, \mathrm{d}\mathscr{H}^2, \tag{5.15}$$

then we have

$$\limsup_{\varepsilon \to 0^+} \left[\bar{\mathsf{E}}_\varepsilon(t_\varepsilon, \check{\mathsf{u}}_\varepsilon, \check{\zeta}_\varepsilon, \check{\boldsymbol{\pi}}_\varepsilon) + \mathsf{R}(\check{\zeta}_\varepsilon - \zeta_\varepsilon, \check{\boldsymbol{\pi}}_\varepsilon - \boldsymbol{\pi}_\varepsilon) \right] \leq \bar{\mathsf{E}}_0(t, \check{\mathsf{u}}, \check{\zeta}, \check{\boldsymbol{\pi}}) + \mathsf{R}(\check{\zeta} - \zeta, \check{\boldsymbol{\pi}} - \boldsymbol{\pi}). \tag{5.16}$$

Proof. First of all we notice that, since the sequence $(t_\varepsilon, \mathsf{u}_\varepsilon, (\zeta_\varepsilon, \boldsymbol{\pi}_\varepsilon))$ is uniformly stable, by the lower semicontinuity Lemma 5.1 we have that $\mathsf{E}_0(t, \mathsf{u}, \zeta, \boldsymbol{\pi}) < +\infty$. Moreover we can assume that right-hand side in (5.14) (and then in (5.16)) be finite, otherwise the result is achieved by simply taking $(\check{\mathsf{u}}_\varepsilon, (\check{\zeta}_\varepsilon, \check{\boldsymbol{\pi}}_\varepsilon)) = (\check{\mathsf{u}}, (\check{\zeta}, \check{\boldsymbol{\pi}}))$ for any $\varepsilon > 0$. This non-resctrictive assumption, together with the finiteness of $\mathsf{E}_0(t, \mathsf{u}, \zeta, \boldsymbol{\pi})$, implies that

$$\mathsf{E}_0(t, \check{\mathsf{u}}, \check{\zeta}, \check{\boldsymbol{\pi}}) < +\infty \quad \text{and} \quad \mathsf{R}(\check{\zeta} - \zeta, \check{\boldsymbol{\pi}} - \boldsymbol{\pi}) < +\infty.$$

In particular then we have $\zeta \geq \check{\zeta}$ a.e. on Γ_{C}. Inspired by [60], let us define

$$\check{\zeta}_\varepsilon := \begin{cases} \dfrac{\zeta_\varepsilon \check{\zeta}}{\zeta} & \text{if } \zeta > 0, \\ 0 & \text{if } \zeta = 0, \end{cases} \quad \text{and} \quad \check{\boldsymbol{\pi}}_\varepsilon := \check{\boldsymbol{\pi}} + \boldsymbol{\pi}_\varepsilon - \boldsymbol{\pi}.$$

Then it is easy to check that $0 \leq \check{\zeta}_\varepsilon \leq 1$ a.e. on Γ_{C}, $\check{\zeta}_\varepsilon \overset{*}{\rightharpoonup} \check{\zeta}$ in $L^\infty(\Gamma_{\mathrm{C}})$ and $\check{\boldsymbol{\pi}}_\varepsilon \rightharpoonup \check{\boldsymbol{\pi}}$ in $W^{1,2}(\Gamma_{\mathrm{C}}; \mathbb{R}^2)$ (in particular, (5.12) and (5.13) are proven). Moreover, since $\check{\zeta}_\varepsilon - \zeta_\varepsilon \leq 0$, then

$$\lim_{\varepsilon \to 0^+} \mathsf{R}(\check{\zeta}_\varepsilon - \zeta_\varepsilon, \check{\boldsymbol{\pi}}_\varepsilon - \boldsymbol{\pi}_\varepsilon) = \lim_{\varepsilon \to 0^+} \int_{\Gamma_{\mathrm{C}}} \mathsf{a}(\zeta_\varepsilon - \check{\zeta}_\varepsilon) + \sigma_{\mathrm{yield}} |\check{\boldsymbol{\pi}} - \boldsymbol{\pi}| \, \mathrm{d}\mathscr{H}^2$$

$$= \int_{\Gamma_{\mathrm{C}}} \mathsf{a}(\zeta - \check{\zeta}) + \sigma_{\mathrm{yield}} |\check{\boldsymbol{\pi}} - \boldsymbol{\pi}| \, \mathrm{d}\mathscr{H}^2 = \mathsf{R}(\check{\zeta} - \zeta, \check{\boldsymbol{\pi}} - \boldsymbol{\pi}).$$

Thus, to prove (5.14) it suffices to deal with the convergence of the energies, that is, it is enough to prove that

$$\limsup_{\varepsilon \to 0^+} \left[\mathsf{E}_\varepsilon(t_\varepsilon, \check{\mathsf{u}}_\varepsilon, \check{\zeta}_\varepsilon, \check{\boldsymbol{\pi}}_\varepsilon) - \mathsf{E}_\varepsilon(t_\varepsilon, \mathsf{u}_\varepsilon, \zeta_\varepsilon, \boldsymbol{\pi}_\varepsilon) \right] \leq \mathsf{E}_0(t, \check{\mathsf{u}}, \check{\zeta}, \check{\boldsymbol{\pi}}) - \mathsf{E}_0(t, \mathsf{u}, \zeta, \boldsymbol{\pi}). \tag{5.17}$$

The sequence $\check{\mathsf{u}}_\varepsilon$ can be constructed following what we did in [21] and in the proof of Lemma (3.1) and which we recall also here for convenience of the reader. For fixed t we let

$$\psi := - \sum_{\alpha, \beta = 1}^2 \frac{\mathbb{C}_{33\alpha\beta} \tilde{e}(\check{\mathsf{u}} + \mathsf{u}_{\mathrm{D}}(t))_{\alpha\beta}}{\mathbb{C}_{3333}},$$

and choose $\psi_\varepsilon \in C_0^\infty(\Omega)$ such that $\psi_\varepsilon \to \psi$ and $\varepsilon \partial \psi_\varepsilon / \partial x_\alpha \to 0$ in $L^2(\Omega)$ for $\alpha = 1, 2$. Set

$$\eta_\varepsilon(x_1, x_2, x_3) := \int_0^{x_3} \psi_\varepsilon(x_1, x_2, s) \, \mathrm{d}s$$

and

$$\left.\begin{array}{ll} (\check{u}_\varepsilon)_\alpha := \check{u}_\alpha, & \alpha = 1, 2, \\ (\check{u}_\varepsilon)_3 := \check{u}_3 + \varepsilon^2 \eta_\varepsilon. \end{array}\right\} \tag{5.18}$$

In this way we have $\check{u}_\varepsilon \in W^{1,2}(\Omega_1 \cup \Omega_2; \mathbb{R}^3)$ and $\check{u}_\varepsilon \to \check{u}$ in $W^{1,2}(\Omega_1 \cup \Omega_2; \mathbb{R}^3)$ (in particular, (5.11) is proven). Since $\mathsf{E}_0(t, \check{u}, \check{\zeta}, \check{\boldsymbol{\pi}}) < +\infty$ then for every ε, by construction, $(t_\varepsilon, \check{u}_\varepsilon, \check{\zeta}_\varepsilon, \check{\boldsymbol{\pi}}_\varepsilon)$ belongs to the effective domain of E_ε and therefore

$$\mathsf{E}_\varepsilon(t_\varepsilon, \check{u}_\varepsilon, \check{\zeta}_\varepsilon, \boldsymbol{\pi}_\varepsilon) = \frac{1}{2} \int_{\Omega_1 \cup \Omega_2} \mathbb{C} e^\varepsilon(\check{u}_\varepsilon + \mathsf{u}_\mathrm{D}(t_\varepsilon)) : e^\varepsilon(\check{u}_\varepsilon + \mathsf{u}_\mathrm{D}(t_\varepsilon)) - 2\mathsf{f}(t_\varepsilon) \cdot (\check{u}_\varepsilon + \mathsf{u}_\mathrm{D}(t_\varepsilon)) \, \mathrm{d}x$$

$$+ \int_{\Gamma_\mathrm{C}} \check{\zeta}_\varepsilon \mathsf{Q}^\varepsilon ([\![\check{u}_\varepsilon]\!] - \mathbb{T}\check{\boldsymbol{\pi}}_\varepsilon) + \frac{\kappa_\mathrm{H}}{2} |\check{\boldsymbol{\pi}}_\varepsilon|^2 + \frac{\kappa_0}{2} |\nabla_\mathrm{S} \check{\boldsymbol{\pi}}_\varepsilon|^2 \, \mathrm{d}\mathcal{H}^2. \tag{5.19}$$

By (3.2) and since $\check{u}$ and u_D are in $W_\mathrm{KL}^{1,2}(\Omega_1 \cup \Omega_2; \mathbb{R}^3)$, we have

$$e^\varepsilon(\check{u}_\varepsilon + \mathsf{u}_\mathrm{D}(t_\varepsilon)) = \begin{pmatrix} e(\check{u} + \mathsf{u}_\mathrm{D}(t_\varepsilon))_{\alpha\beta} & \dfrac{\varepsilon}{2} \dfrac{\partial \eta_\varepsilon}{\partial x_\alpha} \\ \mathrm{sym} & \psi_\varepsilon \end{pmatrix}.$$

Taking the limit as $\varepsilon \to 0^+$ we have

$$\lim_{\varepsilon \to 0^+} \left\| e^\varepsilon(\check{u}_\varepsilon + \mathsf{u}_\mathrm{D}(t_\varepsilon)) - \begin{pmatrix} \tilde{e}(\check{u} + \mathsf{u}_\mathrm{D}(t)) & 0 \\ 0 & -\sum_{\alpha, \beta=1}^2 \mathbb{C}_{33\alpha\beta} \tilde{e}(\check{u} + \mathsf{u}_\mathrm{D}(t))_{\alpha\beta} / \mathbb{C}_{3333} \end{pmatrix} \right\|_{L^2(\Omega_1 \cup \Omega_2; \mathbb{R}^{3\times3})} = 0,$$

and therefore, concerning the bulk part in (5.19), we obtain

$$\lim_{\varepsilon \to 0^+} \int_{\Omega_1 \cup \Omega_2} \mathbb{C} e^\varepsilon(\check{u}_\varepsilon + \mathsf{u}_\mathrm{D}(t_\varepsilon)) : e^\varepsilon(\check{u}_\varepsilon + \mathsf{u}_\mathrm{D}(t_\varepsilon)) \, \mathrm{d}x = \int_{\Omega_1 \cup \Omega_2} \mathbb{C}^0 \tilde{e}(\check{u} + \mathsf{u}_\mathrm{D}(t)) : \tilde{e}(\check{u} + \mathsf{u}_\mathrm{D}(t)) \, \mathrm{d}x,$$

and, by the lower semicontinuity Lemma 5.1, we have

$$\limsup_{\varepsilon \to 0^+} \left[\int_{\Omega_1 \cup \Omega_2} \mathbb{C} e^\varepsilon(\check{u}_\varepsilon + \mathsf{u}_\mathrm{D}(t_\varepsilon)) : e^\varepsilon(\check{u}_\varepsilon + \mathsf{u}_\mathrm{D}(t_\varepsilon)) \, \mathrm{d}x - \int_{\Omega_1 \cup \Omega_2} \mathbb{C} e^\varepsilon(\mathsf{u}_\varepsilon + \mathsf{u}_\mathrm{D}(t_\varepsilon)) : e^\varepsilon(\mathsf{u}_\varepsilon + \mathsf{u}_\mathrm{D}(t_\varepsilon)) \, \mathrm{d}x \right]$$

$$\leq \int_{\Omega_1 \cup \Omega_2} \mathbb{C} \tilde{e}(\check{u} + \mathsf{u}_\mathrm{D}(t)) : \tilde{e}(\check{u} + \mathsf{u}_\mathrm{D}(t)) \, \mathrm{d}x - \int_{\Omega_1 \cup \Omega_2} \mathbb{C} \tilde{e}(\mathsf{u} + \mathsf{u}_\mathrm{D}(t)) : \tilde{e}(\mathsf{u} + \mathsf{u}_\mathrm{D}(t)) \, \mathrm{d}x. \tag{5.20}$$

By the same argument used to prove (5.10) we have

$$\lim_{\varepsilon \to 0^+} \int_{\Gamma_\mathrm{C}} \zeta_\varepsilon \mathsf{Q}^\varepsilon ([\![\mathsf{u}_\varepsilon]\!] - \mathbb{T}\boldsymbol{\pi}_\varepsilon) \, \mathrm{d}\mathcal{H}^2 = \int_{\Gamma_\mathrm{C}} \zeta \mathsf{Q}^0 ([\![\mathsf{u}]\!] - \mathbb{T}\boldsymbol{\pi}) \, \mathrm{d}\mathcal{H}^2 \tag{5.21}$$

and

$$\lim_{\varepsilon \to 0^+} \int_{\Gamma_\mathrm{C}} \check{\zeta}_\varepsilon \mathsf{Q}^\varepsilon ([\![\check{u}_\varepsilon]\!] - \mathbb{T}\check{\boldsymbol{\pi}}_\varepsilon) \, \mathrm{d}\mathcal{H}^2 = \int_{\Gamma_\mathrm{C}} \check{\zeta} \mathsf{Q}^0 ([\![\check{u}]\!] - \mathbb{T}\check{\boldsymbol{\pi}}) \, \mathrm{d}\mathcal{H}^2. \tag{5.22}$$

Since $\boldsymbol{\pi}_\varepsilon \to \boldsymbol{\pi}$ and $\check{\boldsymbol{\pi}}_\varepsilon \to \check{\boldsymbol{\pi}}$ then

$$\lim_{\varepsilon \to 0^+} \int_{\Gamma_\mathrm{C}} \frac{\kappa_\mathrm{H}}{2} |\boldsymbol{\pi}_\varepsilon|^2 \, \mathrm{d}\mathcal{H}^2 = \int_{\Gamma_\mathrm{C}} \frac{\kappa_\mathrm{H}}{2} |\boldsymbol{\pi}|^2 \, \mathrm{d}\mathcal{H}^2 \quad \text{and} \quad \lim_{\varepsilon \to 0^+} \int_{\Gamma_\mathrm{C}} \frac{\kappa_\mathrm{H}}{2} |\check{\boldsymbol{\pi}}_\varepsilon|^2 \, \mathrm{d}\mathcal{H}^2 = \int_{\Gamma_\mathrm{C}} \frac{\kappa_\mathrm{H}}{2} |\check{\boldsymbol{\pi}}|^2 \, \mathrm{d}\mathcal{H}^2. \tag{5.23}$$

Concerning the term involving the gradient, by the so-called binomial trick we have

$$|\nabla_\mathrm{S} \check{\boldsymbol{\pi}}_\varepsilon|^2 - |\nabla_\mathrm{S} \boldsymbol{\pi}_\varepsilon|^2 = (\nabla_\mathrm{S} \check{\boldsymbol{\pi}}_\varepsilon - \nabla_\mathrm{S} \boldsymbol{\pi}_\varepsilon) \cdot (\nabla_\mathrm{S} \check{\boldsymbol{\pi}}_\varepsilon + \nabla_\mathrm{S} \boldsymbol{\pi}_\varepsilon) = (\nabla_\mathrm{S} \check{\boldsymbol{\pi}} - \nabla_\mathrm{S} \boldsymbol{\pi}) \cdot (\nabla_\mathrm{S} \check{\boldsymbol{\pi}}_\varepsilon + \nabla_\mathrm{S} \boldsymbol{\pi}_\varepsilon)$$

and since $\nabla_{\mathrm{s}}\check{\boldsymbol{\pi}}_\varepsilon + \nabla_{\mathrm{s}}\boldsymbol{\pi}_\varepsilon \rightharpoonup \nabla_{\mathrm{s}}\check{\boldsymbol{\pi}} + \nabla_{\mathrm{s}}\boldsymbol{\pi}$ in $L^2(\Gamma_{\mathrm{C}};\mathbb{R}^2)$, then we get

$$\lim_{\varepsilon \to 0^+} \int_{\Gamma_{\mathrm{C}}} \left(|\nabla_{\mathrm{s}}\check{\boldsymbol{\pi}}_\varepsilon|^2 - |\nabla_{\mathrm{s}}\boldsymbol{\pi}_\varepsilon|^2 \right) \mathrm{d}\mathscr{H}^2 = \int_{\Gamma_{\mathrm{C}}} \left(|\nabla_{\mathrm{s}}\check{\boldsymbol{\pi}}|^2 - |\nabla_{\mathrm{s}}\boldsymbol{\pi}|^2 \right) \mathrm{d}\mathscr{H}^2$$

and therefore

$$\lim_{\varepsilon \to 0^+} \int_{\Gamma_{\mathrm{C}}} \frac{\kappa_0}{2} |\nabla_{\mathrm{s}}\check{\boldsymbol{\pi}}_\varepsilon|^2 \,\mathrm{d}\mathscr{H}^2 - \int_{\Gamma_{\mathrm{C}}} \frac{\kappa_0}{2} |\nabla_{\mathrm{s}}\boldsymbol{\pi}_\varepsilon|^2 \,\mathrm{d}\mathscr{H}^2 = \int_{\Gamma_{\mathrm{C}}} \frac{\kappa_0}{2} |\nabla_{\mathrm{s}}\check{\boldsymbol{\pi}}|^2 \,\mathrm{d}\mathscr{H}^2 - \int_{\Gamma_{\mathrm{C}}} \frac{\kappa_0}{2} |\nabla_{\mathrm{s}}\boldsymbol{\pi}|^2 \,\mathrm{d}\mathscr{H}^2. \qquad (5.24)$$

Inequality (5.16) follows by (5.20), (5.21), (5.22), (5.23), and Lemma 3.1. Using moreover (5.24) we finally obtain also (5.14) and the proof is concluded. $\qquad\square$

5.3 Convergence of solutions

The aim of this section is to show, assuming $\mathsf{q}^0_\varepsilon \rightharpoonup \mathsf{q}^0$ in $\mathcal{Q}$, the convergences of (the solutions to) the corresponding quasi-static evolution problems. The notation in use is that of [50]. According to what we have done above, we denote by $\mathcal{Q}$ the topological product of the spaces $\mathcal{U}$ and $\mathcal{Z}$ endowed, respectively, with the weak and the weak* topology. Since $\mathcal{U}$ is reflexive here, its weak topology is also weak*, and thus the convergence in $\mathcal{Q}$ will be denoted simply by $\overset{*}{\rightharpoonup}$. Setting $\mathsf{q} = (\mathsf{u}, z)$ and $z = (\zeta, \boldsymbol{\pi})$, we shall write, for instance, (t, q) in place of (t, u, z) and the latter in place of $(t, \mathsf{u}, \zeta, \boldsymbol{\pi})$.

Our results will be achieved by applying general abstract theorems proven in [19, 44, 50]. In what follows we write and check the assumptions needed to apply those theorems.

The dissipation distance

$$\mathcal{D}(z_1, z_2) = \mathsf{R}(z_2 - z_1)$$

satisfies the following properties, corresponding to [50, Formulas (2.2)–(2.4)].

Pseudo distance:

$$\mathcal{D}(z_1, z_1) = 0 \quad \text{and} \quad \mathcal{D}(z_1, z_3) \le \mathcal{D}(z_1, z_2) + \mathcal{D}(z_2, z_3) \quad \text{for any } z_1, z_2, z_3 \in \mathcal{Z}. \qquad (5.25)$$

Lower semi-continuity of $\mathcal{D}$:

$$\mathcal{D} : \mathcal{Z} \times \mathcal{Z} \to [0, +\infty] \text{ is w*-lower semi-continuous.} \qquad (5.26)$$

Positivity of $\mathcal{D}$:

$$\begin{array}{l} \text{if a sequence } (z_n) \text{ in } \mathcal{Z} \text{ and } z \in \mathcal{Z} \text{ are such that} \\ \min\{\mathcal{D}(z_n, z), \mathcal{D}(z, z_n)\} \to 0, \text{ then } z_n \to z \text{ weakly* in } \mathcal{Z}. \end{array} \qquad (5.27)$$

From (5.26) it follows (2.5) of [50], that is

Lower Γ-limit for $\mathcal{D}$:

$$\begin{array}{l} \text{for any pair of stable sequences } (t_n, \mathsf{q}_n), (\check{t}_n, \check{\mathsf{q}}_n) \text{ such that} \\ (t_n, \mathsf{q}_n) \overset{*}{\rightharpoonup} (t, \mathsf{q}), (\check{t}_n, \check{\mathsf{q}}_n) \overset{*}{\rightharpoonup} (\check{t}, \check{\mathsf{q}}) \text{ in } [0, T] \times \mathcal{Q}, \text{ we have} \\ \mathcal{D}(z, \check{z}) \le \liminf_{n \to +\infty} \mathcal{D}(z_n, \check{z}_n). \end{array} \qquad (5.28)$$

From Korn's inequality, (2.4), (3.4) and (3.5), we find

$$\mathsf{E}_\varepsilon(t, \mathsf{u}, z) \ge \frac{1}{2} \int_{\Omega_1 \cup \Omega_2} \mathbb{C}e^\varepsilon(\mathsf{u} + \mathsf{u}_{\mathrm{D}}(t)) : e^\varepsilon(\mathsf{u} + \mathsf{u}_{\mathrm{D}}(t)) - 2\mathsf{f}^\varepsilon(t) \cdot (\mathsf{u} + \mathsf{u}_{\mathrm{D}}(t)) \,\mathrm{d}x$$

$$\ge c \big\| e(\mathsf{u} + \mathsf{u}_{\mathrm{D}}(t)) \big\|_{L^2}^2 - \frac{1}{2\alpha} \big\| \mathsf{f}(t) \big\|_{L^2}^2 - \frac{\alpha}{2} \big\| \mathsf{u} + \mathsf{u}_{\mathrm{D}}(t) \big\|_{L^2}^2 \ge K \big\| \mathsf{u} \big\|_{W^{1,2}}^2 - C, \qquad (5.29)$$

where $\mathsf{f} = (\mathsf{f}_1, \mathsf{f}_2, \mathsf{f}_3)$, see (3.3). This last inequality, together with a similar computation for E_0, shows that the set $\bigcup_{\varepsilon \ge 0}\{\mathsf{q} \in \mathcal{Q} : \mathsf{E}_\varepsilon(t, \mathsf{q}) \le E\}$ is weakly relatively compact. Moreover, for any $\varepsilon \ge 0$ the functionals $\mathsf{E}_\varepsilon(t, \cdot)$ are weakly lower semicontinuous in $\mathcal{Q}$ due to the convexity of the bulk part of the energy and Lemma 3.1. Thus the sublevels are also closed and the following property (corresponding to (2.6) of [50]) holds

Compactness of energy sublevels:

for all $t \in [0,T]$ and all $E \in \mathbb{R}$ we have

(i) $\{\mathsf{q} \in \mathcal{Q} : \mathsf{E}_\varepsilon(t,\mathsf{q}) \leq E\}$ is compact for any $\varepsilon \geq 0$;

(ii) $\bigcup_{\varepsilon \geq 0}\{\mathsf{q} \in \mathcal{Q} : \mathsf{E}_\varepsilon(t,\mathsf{q}) \leq E\}$ is relatively compact. $\qquad(5.30)$

Since f and w are continuously differentiable with respect to t (see Section 3.1), then $\mathsf{E}_\varepsilon(\cdot,\mathsf{q}) \in C^1([0,T])$ for all $\varepsilon \geq 0$ and all $\mathsf{q} \in \mathcal{Q}$ for which $\mathsf{E}_\varepsilon(\cdot,\mathsf{q}) < +\infty$.

If $\mathsf{E}_\varepsilon(s,\mathsf{u},z) < +\infty$ for $s \in [0,T]$, then we have

$$\partial_t \mathsf{E}_\varepsilon(t,\mathsf{u},z) = \int_{\Omega_1 \cup \Omega_2} \mathbb{C}e^\varepsilon(\dot{\mathsf{u}}_\mathrm{D}(t)){:}e^\varepsilon(\mathsf{u}{+}\mathsf{u}_\mathrm{D}(t)) - \dot{\mathsf{f}}^\varepsilon(t){\cdot}(\mathsf{u}{+}\mathsf{u}_\mathrm{D}(t)) - \mathsf{f}^\varepsilon(t){\cdot}\dot{\mathsf{u}}_\mathrm{D}(t)\,\mathrm{d}x \qquad(5.31)$$

and, since $(e(\dot{\mathsf{u}}_\mathrm{D}))_{i3} = 0$ (see (3.5)), by inequality (5.29) we have

$$\left|\partial_t \mathsf{E}_\varepsilon(t,\mathsf{u},z)\right| \leq c\Big(\left\|e(\dot{\mathsf{u}}_\mathrm{D})(t)\right\|_{L^2}^2 + \|\dot{\mathsf{f}}(t)\|_{L^2}^2 + \left\|\mathsf{u}_\mathrm{D}(t)\right\|_{L^2}^2 + \left\|\mathsf{f}(t)\right\|_{L^2}^2 + \left\|\dot{\mathsf{u}}_\mathrm{D}(t)\right\|_{L^2}^2 + \mathsf{E}_\varepsilon(t,\mathsf{u},z) + C\Big),$$

which, together with a similar computation for E_0, leads to (see (2.7) of [50])

Uniform control of the power $\partial_t \mathsf{E}_\varepsilon$:

there exist $c_0^E \in \mathbb{R}$ and $c_1^E > 0$ such that

for any $\varepsilon \geq 0$, $t \in [0,T]$ and $\mathsf{q} \in \mathcal{Q}$,

if $\mathsf{E}_\varepsilon(t,\mathsf{q}) < +\infty$ then $\mathsf{E}_\varepsilon(\cdot,\mathsf{q}) \in C^1([0,T])$ and $\qquad(5.32)$

$|\partial_t \mathsf{E}_\varepsilon(s,\mathsf{q})| \leq c_1^E(c_0^E + \mathsf{E}_\varepsilon(s,\mathsf{q}))$ for all $s \in [0,T]$.

By definition of E_0 (given in (3.17)) it follows that if $\mathsf{E}_0(0,\mathsf{u},z)$ is finite then $\mathsf{u} \in W_{\mathrm{KL}}^{1,2}(\Omega_1 \cup \Omega_2; \mathbb{R}^3)$ and thus $\mathsf{E}_0(t,\mathsf{u},z)$ is finite for every $t \in [0,T]$. Since f and w are C^1 with respect to t, condition (2.8) of [50] is satisfied, namely

Uniform time-continuity of the power $\partial_t \mathsf{E}_{0,\kappa}$:

for every $\eta > 0$ and $E \in \mathbb{R}$ there exists $\delta > 0$ such that $\qquad(5.33)$

$\mathsf{E}_0(0,\mathsf{q}) \leq E$, $|t_1 - t_2| < \delta \Rightarrow |\partial_t \mathsf{E}_0(t_1,\mathsf{q}) - \partial_t \mathsf{E}_0(t_2,\mathsf{q})| < \eta$.

By Lemma 5.1 we get the following property (2.10) of [50]

Lower Γ-limit for $\mathsf{E}_{\varepsilon,\kappa}$:

for any uniformly stable sequence $(t_\varepsilon, \mathsf{q}_\varepsilon)$ such that

$(t_\varepsilon, \mathsf{q}_\varepsilon) \overset{*}{\rightharpoonup} (t,\mathsf{q})$ in $[0,T] \times \mathcal{Q}$, we have $\qquad(5.34)$

$\mathsf{E}_0(t,\mathsf{q}) \leq \liminf_{\varepsilon \to 0^+} \mathsf{E}_\varepsilon(t_\varepsilon, \mathsf{q}_\varepsilon)$.

The following lemma essentially corresponds to property (2.9) of [50]; the only difference is that we establish the convergence in the open interval $(0,T)$ instead of its closure. This fact will not affect the arguments used in the sequel.

Lemma 5.3 (Conditioned continuous convergence of the power). *Let $(t,\mathsf{q}) \in (0,T) \times \mathcal{Q}$ and let $(t_\varepsilon, \mathsf{q}_\varepsilon)$ be a uniformly stable sequence. If $(t_\varepsilon, \mathsf{q}_\varepsilon) \overset{*}{\rightharpoonup} (t,\mathsf{q})$ in $[0,T] \times \mathcal{Q}$, then*

$$\partial_t \mathsf{E}_\varepsilon(t_\varepsilon, \mathsf{q}_\varepsilon) \to \partial_t \mathsf{E}_0(t,\mathsf{q}).$$

Proof. Since $\partial_t \mathsf{E}_\varepsilon = \partial_t \bar{\mathsf{E}}_\varepsilon$ for every $\varepsilon \geq 0$, where $\bar{\mathsf{E}}_\varepsilon$ has been defined in (5.15), then we can equivalently prove that

$$\partial_t \bar{\mathsf{E}}_\varepsilon(t_\varepsilon, \mathsf{q}_\varepsilon) \to \partial_t \bar{\mathsf{E}}_0(t,\mathsf{q}).$$

The proof can now be done by following exactly the same arguments of the proof of Lemma 5.2 of [21], starting from the convergence property stated in the following lemma. $\qquad\square$

Lemma 5.4. *Let* $(t, \mathsf{q}) \in (0, T) \times \mathcal{Q}$ *and let* $(t_\varepsilon, \mathsf{q}_\varepsilon)$ *be a uniformly stable sequence w.r. to* (E_ε) *and* (S_ε). *If* $(t_\varepsilon, \mathsf{q}_\varepsilon) \overset{*}{\rightharpoonup} (t, \mathsf{q})$ *in* $[0, T] \times \mathcal{Q}$, *then*

$$\bar{\mathsf{E}}_\varepsilon(t_\varepsilon, \mathsf{q}_\varepsilon) \to \bar{\mathsf{E}}_0(t, \mathsf{q}) \qquad as \quad \varepsilon \to 0^+. \tag{5.35}$$

Proof. Let $\mathsf{q} =: (\mathsf{u}, \zeta, \boldsymbol{\pi})$ and $\mathsf{q}_\varepsilon =: (\mathsf{u}_\varepsilon, \zeta_\varepsilon, \boldsymbol{\pi}_\varepsilon)$. Being uniformly stable with respect to (E_ε) and (S_ε), the sequence $(t_\varepsilon, \mathsf{q}_\varepsilon)$ satisfies the assumptions of Lemma 5.2 which we apply now with the choice $\check{\mathsf{u}} = \mathsf{u}$, $\check{\zeta} = \zeta$ and $\check{\boldsymbol{\pi}} = \boldsymbol{\pi}$. Hence there exist $\check{\mathsf{q}}_\varepsilon = (\check{\mathsf{u}}_\varepsilon, \check{z}_\varepsilon) = (\check{\mathsf{u}}_\varepsilon, \check{\zeta}_\varepsilon, \check{\boldsymbol{\pi}}_\varepsilon) \in \mathcal{Q}$ with $\check{\boldsymbol{\pi}}_\varepsilon = \boldsymbol{\pi}_\varepsilon - \check{\boldsymbol{\pi}} - \boldsymbol{\pi} = \boldsymbol{\pi}_\varepsilon$ such that

$$\check{\mathsf{q}}_\varepsilon \overset{*}{\rightharpoonup} \mathsf{q} \text{ in } \mathcal{Q},$$
$$\limsup_{\varepsilon \to 0^+} \left[\bar{\mathsf{E}}_\varepsilon(t_\varepsilon, \check{\mathsf{q}}_\varepsilon) + \mathsf{R}(\check{\mathsf{q}}_\varepsilon - \mathsf{q}_\varepsilon) \right] \leq \bar{\mathsf{E}}_0(t, \mathsf{q}). \tag{5.36}$$

By the stability of $(t_\varepsilon, \mathsf{q}_\varepsilon)$ with respect to (E_ε) and (S_ε) we have

$$\bar{\mathsf{E}}_\varepsilon(t_\varepsilon, \mathsf{q}_\varepsilon) + \int_{\Gamma_{\mathrm{C}}} \frac{\kappa_0}{2} |\nabla_{\mathrm{s}} \boldsymbol{\pi}_\varepsilon|^2 \, \mathrm{d}\mathscr{H}^2 \leq \bar{\mathsf{E}}_\varepsilon(t_\varepsilon, \check{\mathsf{q}}_\varepsilon) + \int_{\Gamma_{\mathrm{C}}} \frac{\kappa_0}{2} |\nabla_{\mathrm{s}} \check{\boldsymbol{\pi}}_\varepsilon|^2 \, \mathrm{d}\mathscr{H}^2 + \mathsf{R}(\check{\mathsf{q}}_\varepsilon - \mathsf{q}_\varepsilon)$$
$$= \bar{\mathsf{E}}_\varepsilon(t_\varepsilon, \check{\mathsf{q}}_\varepsilon) + \int_{\Gamma_{\mathrm{C}}} \frac{\kappa_0}{2} |\nabla_{\mathrm{s}} \boldsymbol{\pi}_\varepsilon|^2 \, \mathrm{d}\mathscr{H}^2 + \mathsf{R}(\check{\mathsf{q}}_\varepsilon - \mathsf{q}_\varepsilon)$$

from which we get

$$\bar{\mathsf{E}}_\varepsilon(t_\varepsilon, \mathsf{q}_\varepsilon) \leq \bar{\mathsf{E}}_\varepsilon(t_\varepsilon, \check{\mathsf{q}}_\varepsilon) + \mathsf{R}(\check{\mathsf{q}}_\varepsilon - \mathsf{q}_\varepsilon)$$

which, together with (5.36) gives

$$\limsup_{\varepsilon \to 0^+} \bar{\mathsf{E}}_\varepsilon(t_\varepsilon, \mathsf{q}_\varepsilon) \leq \bar{\mathsf{E}}_0(t, \mathsf{q}).$$

Hence (5.35) follows from the inequality above and an adaptation of Lemma 5.1 to $\bar{\mathsf{E}}_\varepsilon$. $\qquad\square$

By [50, Proposition 2.2] we get that Lemma 5.2 implies property (2.11) of [50], namely

Conditioned upper-semicontinuity of stable sets:

     - for any uniformly stable sequence $(t_\varepsilon, \mathsf{q}_\varepsilon)$ w. r. to (E_ε) and (S_ε) such that
$\quad(t_\varepsilon, \mathsf{q}_\varepsilon) \overset{*}{\rightharpoonup} (t, \mathsf{q})$ in $[0, T] \times \mathcal{Q}$ we have that $\mathsf{q} \in \mathsf{S}_0(t)$. $\hspace{2cm}$ (5.37)

    The existence of energetic solutions associated with the functionals E_ε and R, for fixed $\varepsilon > 0$, has been proven in [60]. An alternative proof could be made as in [21, Theorem 5.4], based on a general existence theorem of Mielke [46], see also [19, 44, 50].

    We are now in a position to state our main dimension reduction result.

Theorem 5.5 (Convergence as $\varepsilon \to 0$). *Let* $\mathsf{q}_0 = (\mathsf{u}_0, z_0) \in \mathcal{Q}$ *and, for any* $\varepsilon > 0$, $\mathsf{q}_{0,\varepsilon} = (\mathsf{u}_{0,\varepsilon}, z_{0,\varepsilon}) \in \mathsf{S}_\varepsilon(0)$ *with* $\mathsf{q}_{0,\varepsilon} \overset{*}{\rightharpoonup} \mathsf{q}_0$ *and* $\mathsf{E}_\varepsilon(0, \mathsf{q}_{0,\varepsilon}) \to \mathsf{E}_0(0, \mathsf{q}_0)$ *as* $\varepsilon \to 0$, *let further* $\mathsf{q}_\varepsilon = (\mathsf{u}_\varepsilon, z_\varepsilon) : [0, T] \to \mathcal{Q}$ *be an energetic solution to the problem* $(\mathcal{Q}, \mathsf{E}_\varepsilon, \mathsf{R}, \mathsf{q}_\varepsilon(0))$. *Then there exist* $\mathsf{q} = (\mathsf{u}, z) : [0, T] \to \mathcal{Q}$ *such that, up to a subsequence,*

$$\mathsf{E}_\varepsilon(t, \mathsf{q}_\varepsilon(t)) \to \mathsf{E}_0(t, \mathsf{q}(t)) \qquad\qquad\quad \textit{for every } t \in [0, T], \tag{5.38a}$$
$$\mathsf{R}(z_\varepsilon(t) - z_\varepsilon(0)) \to \mathsf{R}(z(t) - z(0)) \qquad \textit{for every } t \in [0, T], \tag{5.38b}$$
$$\partial_t \mathsf{E}_\varepsilon(\cdot, \mathsf{q}_\varepsilon(\cdot)) \to \partial_t \mathsf{E}_0(\cdot, \mathsf{q}(\cdot)) \qquad\quad\;\; \textit{in } L^1(0, T), \tag{5.38c}$$
$$\zeta_\varepsilon(t) \overset{*}{\rightharpoonup} \zeta(t) \qquad\qquad\qquad\qquad\quad\;\; \textit{in } L^\infty(\Gamma_{\mathrm{C}}) \textit{ for every } t \in [0, T], \tag{5.38d}$$
$$\boldsymbol{\pi}_\varepsilon(t) \to \boldsymbol{\pi}(t) \qquad\qquad\qquad\qquad\;\; \textit{in } W^{1,2}(\Gamma_{\mathrm{C}}; \mathbb{R}^2) \textit{ for every } t \in [0, T], \tag{5.38e}$$
$$\mathsf{u}_\varepsilon(t) \rightharpoonup \mathsf{u}(t) \qquad\qquad\qquad\qquad\;\;\; \textit{in } W^{1,2}(\Omega_1 \cup \Omega_2; \mathbb{R}^3) \textit{ for every } t \in [0, T]. \tag{5.38f}$$

Moreover, any q *obtained in this way is an energetic solution to the problem* $(\mathcal{U} \times \mathcal{Z}, \mathsf{E}_0, \mathsf{R}, \mathsf{q}_0)$.

Proof. Since $t \mapsto \mathsf{q}_\varepsilon(t) = (\mathsf{u}_\varepsilon(t), z_\varepsilon(t))$ is an energetic solution and the power is controlled uniformly in ε, cf. (5.32), by a Gronwall-inequality argument, it can be shown (see [19, 44, 50]) that for every $t \in [0, T]$ the sequence $\mathsf{E}_\varepsilon(t, \mathsf{u}_\varepsilon(t), z_\varepsilon(t))$ is bounded uniformly in ε; hence in particular (t, q_ε) is a uniformly stable sequence. Hence, from the uniform coercivity of $\mathsf{E}_\varepsilon(t, \cdot, \cdot)$ and Korn's inequality (see (5.29)), we have that, for every $t \in [0, T]$

$$(\boldsymbol{\pi}_\varepsilon(t)) \text{ is uniformly bounded in } W^{1,2}(\Gamma_\mathrm{C}; \mathbb{R}^2),$$
$$(\mathsf{u}_\varepsilon(t)) \text{ is uniformly bounded in } W^{1,2}(\Omega_1 \cup \Omega_2; \mathbb{R}^3),$$

and, but this is trivial since $\zeta_\varepsilon \in [0, 1]$,

$$(\zeta_\varepsilon(t)) \text{ is uniformly bounded in } L^\infty(\Gamma_\mathrm{C}).$$

By applying a Helly's type theorem (namely [50, Theorem A.1]) to the sequence $(z_\varepsilon) = (\zeta_\varepsilon, \boldsymbol{\pi}_\varepsilon)$, we have that there exist $\zeta \in L^\infty(\Gamma_\mathrm{C})$ and $\boldsymbol{\pi} \in W^{1,2}(\Gamma_\mathrm{C}; \mathbb{R}^2)$ such that, up to a subsequence (not relabeled)

$$\zeta_\varepsilon(t) \overset{*}{\rightharpoonup} \zeta(t) \quad \text{in } L^\infty(\Gamma_\mathrm{C}), \tag{5.39}$$

$$\boldsymbol{\pi}_\varepsilon(t) \overset{*}{\rightharpoonup} \boldsymbol{\pi}(t) \quad \text{in } W^{1,2}(\Gamma_\mathrm{C}; \mathbb{R}^2) \tag{5.40}$$

for every $t \in [0, T]$. We have thus proven (5.38d) and the weak convergence in (5.38e).

Moreover, for every $t \in [0, T]$ there exists a subsequence (ε^t) such that

$$\mathsf{u}_{\varepsilon^t}(t) \rightharpoonup \mathsf{u}(t) \quad \text{in } W^{1,2}(\Omega_1 \cup \Omega_2; \mathbb{R}^3), \tag{5.41}$$

and

$$\theta(t) := \limsup_{\varepsilon \to 0^+} \partial_t \mathsf{E}_\varepsilon(t, \mathsf{q}_\varepsilon(t)) = \lim_{\varepsilon^t \to 0} \partial_t \mathsf{E}_{\varepsilon^t}(t, \mathsf{q}_{\varepsilon^t}(t)). \tag{5.42}$$

From (5.39), (5.40), (5.41), (5.42) and Lemma 5.3 it follows that

$$\theta(t) = \partial_t \mathsf{E}_0(t, \mathsf{u}(t), z(t)), \tag{5.43}$$

from which (5.38c) follows. By [50, Theorem 3.1] and its proof we deduce that $\mathsf{q}(t) := (\mathsf{u}(t), z(t))$ is an energetic solution to the problem $(\mathcal{U} \times \mathcal{Z}, \mathsf{E}_0, \mathsf{R}, \mathsf{q}(0))$. By the stability inequality for the limit problem and the strict convexity of the map $\mathsf{u} \mapsto \mathsf{E}_0(t, \mathsf{u}, z)$, the function u is uniquely determined by z. Hence the convergence in (5.41) holds for the whole (sub)sequence ε, that is (5.38f).

Let us prove (5.38b). Since $(\mathsf{u}_\varepsilon, z_\varepsilon)$ is an energetic solution, from the energy balance follows that $\mathrm{Diss}_\mathsf{R}(z_\varepsilon, [0, t]) < +\infty$. Hence, by definition, for any partition $\{t_j : j = 1, \ldots, N\}$ of $[0, t]$ we have

$$\sum_{j=1}^N \mathsf{R}(\zeta_\varepsilon(t_j) - \zeta_\varepsilon(t_{j-1}), \boldsymbol{\pi}_\varepsilon(t_j) - \boldsymbol{\pi}_\varepsilon(t_{j-1})) < +\infty$$

which implies that the map $t \mapsto \zeta_\varepsilon(t)$ is non-increasing for the partial ordering "$\leq$ a.e.", hence $\zeta_\varepsilon(t) - \zeta_\varepsilon(0) \leq 0$ a.e. on Γ_C. Then, by (5.39) and (5.40) we have

$$\mathsf{R}(\zeta_\varepsilon(t) - \zeta_\varepsilon(0), \boldsymbol{\pi}_\varepsilon(t) - \boldsymbol{\pi}_\varepsilon(0)) = \int_{\Gamma_\mathrm{C}} \mathsf{a}(\zeta_\varepsilon(0) - \zeta_\varepsilon(t)) + \sigma_{\mathrm{yield}} |\boldsymbol{\pi}_\varepsilon(t) - \boldsymbol{\pi}_\varepsilon(0)| \, \mathrm{d}\mathscr{H}^2 \to \mathsf{R}(\zeta(t) - \zeta(0), \boldsymbol{\pi}(t) - \boldsymbol{\pi}(0))$$

that is (5.38b).

Let us prove the strong convergence in (5.38e). Since, as already remarked, $\mathsf{q}(t) = (\mathsf{u}(t), z(t))$ is an energetic solution to the problem $(\mathcal{U} \times \mathcal{Z}, \mathsf{E}_0, \mathsf{R}, \mathsf{q}(0))$, then the energy balance

$$\mathsf{E}_0(t, \mathsf{q}(t)) + \mathrm{Diss}_\mathsf{R}(z, [0, t]) = \mathsf{E}_0(0, \mathsf{q}_0) + \int_0^t \partial_s \mathsf{E}_0(s, \mathsf{q}(s)) \, \mathrm{d}s$$

holds true. On the other hand, by the definition of $\bar{\mathsf{E}}$ and since $\mathsf{q}_\varepsilon = (\mathsf{u}_\varepsilon, z_\varepsilon)$ is an energetic solution to the problem $(\mathcal{Q}, \mathsf{E}_\varepsilon, \mathsf{R}, \mathsf{q}_\varepsilon(0))$, for any $\varepsilon > 0$ we have also

$$\mathsf{E}_\varepsilon(t, \mathsf{q}_\varepsilon(t)) + \mathrm{Diss}_\mathsf{R}(z_\varepsilon, [0,t]) = \mathsf{E}_\varepsilon(0, \mathsf{q}_{0,\varepsilon}) + \int_0^t \partial_s \mathsf{E}_\varepsilon(s, \mathsf{q}_\varepsilon(s)) \, \mathrm{d}s. \tag{5.44}$$

Substituting

$$\mathsf{E}_\varepsilon(t, \mathsf{q}_\varepsilon(t)) = \bar{\mathsf{E}}_\varepsilon(t, \mathsf{q}_\varepsilon(t)) + \int_{\Gamma_\mathrm{C}} \frac{\kappa_0}{2} |\nabla_\mathrm{s} \boldsymbol{\pi}_\varepsilon|^2 \, \mathrm{d}\mathscr{H}^2$$

in (5.44) we find

$$\int_{\Gamma_\mathrm{C}} \frac{\kappa_0}{2} |\nabla_\mathrm{s} \boldsymbol{\pi}_\varepsilon|^2 \, \mathrm{d}\mathscr{H}^2 = \mathsf{E}_\varepsilon(0, \mathsf{q}_{0,\varepsilon}) - \bar{\mathsf{E}}_\varepsilon(t, \mathsf{q}_\varepsilon(t)) + \mathrm{Diss}_\mathsf{R}(z_\varepsilon, [0,t]) + \int_0^t \partial_s \mathsf{E}_\varepsilon(s, \mathsf{q}_\varepsilon(s)) \, \mathrm{d}s.$$

Taking the limit as $\varepsilon \to 0^+$ and observing that

— $\mathsf{E}_\varepsilon(0, \mathsf{q}_{0,\varepsilon}) \to \mathsf{E}_0(0, \mathsf{q}_0)$ by assumption,

— $\bar{\mathsf{E}}_\varepsilon(t, \mathsf{q}_\varepsilon(t)) \to \bar{\mathsf{E}}_0(t, \mathsf{q}(t))$ by Lemma 5.4 (the fact that $(t, \mathsf{q}_\varepsilon)$ is uniformly stable has been remarked at the beginning of the proof),

— $\mathrm{Diss}_\mathsf{R}(z_\varepsilon, [0,t]) \to \mathrm{Diss}_\mathsf{R}(z_0, [0,t])$ which easily follows by (5.38b),

— $\int_0^t \partial_s \mathsf{E}_\varepsilon(s, \mathsf{q}_\varepsilon(s)) \, \mathrm{d}s \to \int_0^t \partial_s \mathsf{E}_0(s, \mathsf{q}(s)) \, \mathrm{d}s$ by (5.38c)

then we have

$$\lim_{\varepsilon \to 0^+} \int_{\Gamma_\mathrm{C}} \frac{\kappa_0}{2} |\nabla_\mathrm{s} \boldsymbol{\pi}_\varepsilon|^2 \, \mathrm{d}\mathscr{H}^2 = \mathsf{E}_0(0, \mathsf{q}_0(t)) - \bar{\mathsf{E}}_0(t, \mathsf{q}(t)) + \mathrm{Diss}_\mathsf{R}(z_0, [0,t]) + \int_0^t \partial_s \mathsf{E}_0(s, \mathsf{q}(s)) \, \mathrm{d}s$$

$$= \mathsf{E}_0(0, \mathsf{q}(t)) - \bar{\mathsf{E}}_0(t, \mathsf{q}(t)) = \int_{\Gamma_\mathrm{C}} \frac{\kappa_0}{2} |\nabla_\mathrm{s} \boldsymbol{\pi}|^2 \, \mathrm{d}\mathscr{H}^2.$$

Together with the weak convergence, already proven, this implies the strong convergence stated in (5.38e).

Finally, (5.38a) follows by the convergence $\bar{\mathsf{E}}_\varepsilon(t, \mathsf{q}_\varepsilon(t)) \to \bar{\mathsf{E}}_0(t, \mathsf{q}(t))$, the definition of $\bar{\mathsf{E}}_\varepsilon$ and the strong convergence of $\boldsymbol{\pi}_\varepsilon$ to $\boldsymbol{\pi}$. $\qquad\square$

Arguing as in Section 4 we can provide a purely 2D formulation of the limit problem on Γ_C in which the stored energy is

$$\widehat{\mathsf{E}}_0(t, \rho, \xi, z) := \begin{cases} \dfrac{1}{2} \displaystyle\int_{\Gamma_\mathrm{C}} \sum_{\ell=1,2} \Big(\dfrac{h_\ell}{2} \mathbb{C}^0 \tilde{e}(\rho^\ell + \rho_\mathrm{D}){:}\tilde{e}(\rho^\ell + \rho_\mathrm{D}) + (-1)^{\ell+1} \dfrac{h_\ell^2}{8} \mathbb{C}^0 \tilde{e}(\rho^\ell + \rho_\mathrm{D}){:}\nabla^2(\xi^\ell + \xi_\mathrm{D}) \\[2ex] \qquad + \dfrac{h_\ell^3}{24} \mathbb{C}^0 \nabla^2(\xi^\ell + \xi_\mathrm{D}){:}\nabla^2(\xi^\ell + \xi_\mathrm{D}) - \varphi_3^0(\xi^\ell + \xi_\mathrm{D}) - \varphi_\alpha^0(\rho_\alpha^\ell + [\rho_\mathrm{D}]_\alpha) + \varphi_\alpha^1 \dfrac{\partial}{\partial x_\alpha}(\xi^\ell + \xi_\mathrm{D}) \Big) \\[2ex] \qquad + \zeta 1_0(q_\tau) \kappa_\tau |\rho^1 - \rho^2 - \boldsymbol{\pi}|^2 + \zeta 1_0(q_\nu) \kappa_\nu |\xi^1 - \xi^2|^2 \, \mathrm{d}\mathscr{H}^2 \qquad \text{if } (\rho, \xi, \zeta) \in \widehat{\mathsf{A}}_{\mathrm{KL}}^{\mathrm{ad}}, \\[2ex] +\infty \qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad \text{else}, \end{cases}$$

where

$$\widehat{\mathsf{A}}_{\mathrm{KL}}^{\mathrm{ad}} := \Big\{ (\rho, \xi, \zeta) \in W^{1,2}(\Gamma_\mathrm{C}; \mathbb{R}^2)^2 \times W^{2,2}(\Gamma_\mathrm{C})^2 \times L^\infty(\Gamma_\mathrm{C}) : 0 \le \zeta \le 1, \ \xi^1 \ge \xi^2 \ \text{a.e. on } \Gamma_\mathrm{C},$$

$$z|\rho^1 - \rho^2| = 0 \text{ if } q_\tau < 0, \ z(\xi^1 - \xi^2) = 0 \text{ if } q_\nu < 0,$$

$$\rho^\ell|_{\gamma_{\mathrm{D}\ell}} = 0, \ \ \xi^\ell|_{\gamma_{\mathrm{D}\ell}} = \nabla \xi^\ell|_{\gamma_{\mathrm{D}\ell}} \cdot \nu = 0 \text{ a.e. on } \gamma_{\mathrm{D}\ell}, \ \ \ell = 1,2 \Big\},$$

and the dissipation R is given in (5.1b).
