REGULARITY OF AREA MINIMIZING CURRENTS III: 
BLOW-UP

CAMILLO DE LEllIS AND EMANUELE SPADARO

Abstract. This is the last of a series of three papers in which we give a new, shorter proof of a slightly improved version of Almgren’s partial regularity of area minimizing currents in Riemannian manifolds. Here we perform a blow-up analysis deducing the regularity of area minimizing currents from that of Dir-minimizing multiple valued functions.

0. Introduction

In this paper we complete the proof of a slightly improved version of the celebrated Almgren’s partial regularity result for area minimizing currents in a Riemannian manifold (see [1]), namely Theorem 0.3 below.

Assumption 0.1. Let \( \varepsilon_0 \in ]0, 1[ \), \( m, \bar{n} \in \mathbb{N} \setminus \{0\} \) and \( l \in \mathbb{N} \). We denote by

\begin{align*}
(M) & \quad \Sigma \subset \mathbb{R}^{m+n} = \mathbb{R}^{m+\bar{n}+l} \text{ an embedded } (m + \bar{n}) \text{-dimensional submanifold of class } C^{3, \varepsilon_0}; \\
(C) & \quad T \text{ an integral current of dimension } m \text{ with compact support } \text{spt}(T) \subset \Sigma, \text{ area minimizing in } \Sigma.
\end{align*}

In this paper we follow the notation of [4] concerning balls, cylinders and disks. In particular \( B_r(x) \subset \mathbb{R}^{m+n} \) will denote the Euclidean ball of radius \( r \) and center \( x \).

Definition 0.2. For \( T \) and \( \Sigma \) as in Assumption 0.1 we define

\begin{align*}
\text{Reg}(T) := \{ x \in \text{spt}(T) : \text{spt}(T) \cap B_r(x) \text{ is a } C^{3, \varepsilon_0} \text{ submanifold for some } r > 0 \}, & \quad (0.1) \\
\text{Sing}(T) := \text{spt}(T) \setminus (\text{spt}(\partial T) \cup \text{Reg}(T)), & \quad (0.2)
\end{align*}

The partial regularity result proven first by Almgren [1] under the more restrictive hypothesis \( \Sigma \in C^5 \) gives an estimate on the Hausdorff dimension \( \dim_H(\text{Sing}(T)) \) of \( \text{Sing}(T) \).

Theorem 0.3. \( \dim_H(\text{Sing}(T)) \leq m - 2 \) for any \( m, \bar{n}, l, T \) and \( \Sigma \) as in Assumption 0.1.

In this note we complete the proof of Theorem 0.3, based on our previous works [3, 5, 6, 4], thus providing a new, much shorter, account of one of the most fundamental regularity result in geometric measure theory; we refer to [6] for an extended general introduction to all these works. The proof is carried by contradiction: in the sequel we will always assume the following.

Assumption 0.4 (Contradiction). There exist \( m \geq 2, \bar{n}, l, \Sigma \) and \( T \) as in Assumption 0.1 such that \( \mathcal{H}^{m-2+\alpha}(\text{Sing}(T)) > 0 \) for some \( \alpha > 0 \).
The hypothesis $m \geq 2$ in Assumption 0.4 is justified by the well-known fact that $\text{Sing}(T) = \emptyset$ when $m = 1$ (in this case $\text{spt}(T) \setminus \text{spt}(\partial T)$ is locally the union of finitely many non-intersecting geodesic segments). Starting from Assumption 0.4, we make a careful blow-up analysis, split in the following steps.

0.1. Flat tangent planes. We first reduce to flat blow-ups around a given point, which in the sequel is assumed to be the origin. These blow-ups will also be chosen so that the size of the singular set satisfies a uniform estimate from below (cp. Section 1).

0.2. Intervals of flattening. For appropriate rescalings of the current around the origin we take advantage of the center manifold constructed in [4], which gives a good approximation of the average of the sheets of the current at some given scale. However, since it might fail to do so at different scales, in Section 2 we introduce a stopping condition for the center manifolds and define appropriate intervals of flattening $I_j = [s_j, t_j]$. For each $j$ we construct a different center manifold $\mathcal{M}_j$ and approximate the (rescaled) current with a suitable multi-valued map on the normal bundle of $\mathcal{M}_j$.

0.3. Finite order of contact. A major difficulty in the analysis is to prove that the minimizing current has finite order of contact with the center manifold. To this aim, in analogy with the case of harmonic multiple valued functions (cp. [3, Section 3.4]), we introduce a variant of the frequency function and prove its almost monotonicity and boundedness. This analysis, carried in Sections 3, 4 and 5, relies on the variational formulas for images of multiple valued maps as computed in [5] and on the careful estimates of [4]. Our frequency function differs from that of Almgren and allows for simpler estimates.

0.4. Convergence to Dir-minimizer and contradiction. Based on the previous steps, we can blow-up the Lipschitz approximations from the center manifold $\mathcal{M}_j$ in order to get a limiting Dir-minimizing function on a flat $m$-dimensional domain. We then show that the singularities of the rescaled currents converge to singularities of that limiting Dir-minimizer, contradicting the partial regularity of [3, Section 3.6] and, hence, proving Theorem 0.3.

Acknowledgments. The research of Camillo De Lellis has been supported by the ERC grant agreement RAM (Regularity for Area Minimizing currents), ERC 306247. The authors are warmly thankful to Bill Allard for several enlightening conversations and his constant support.

1. Flat tangent cones

Definition 1.1 ($Q$-points). For $Q \in \mathbb{N}$, we denote by $D_Q(T)$ the points of density $Q$ of the current $T$, and set 
$$\text{Reg}_Q(T) := \text{Reg}(T) \cap D_Q(T) \quad \text{and} \quad \text{Sing}_Q(T) := \text{Sing}(T) \cap D_Q(T).$$

Definition 1.2 (Tangent cones). For any $r > 0$ and $x \in \mathbb{R}^{m+n}$, $\iota_{x,r} : \mathbb{R}^{m+n} \to \mathbb{R}^{m+n}$ is the map $y \mapsto \frac{y-x}{r}$ and $T_{x,r} := (\iota_{x,r})_\ast T$. The classical monotonicity formula (see [10] and [6, Lemma A.1]) implies that, for every $r_k \downarrow 0$ and $x \in \text{spt}(T) \setminus \text{spt}(\partial T)$, there is a subsequence (not relabeled) for which $T_{x,r_k}$ converges to an integral cycle $S$ which is a cone
(i.e., $S_{0,r} = S$ for all $r > 0$ and $\partial S = 0$) and is (locally) area-minimizing in $\mathbb{R}^{m+n}$. Such a cone will be called, as usual, a tangent cone to $T$ at $x$.

Fix $\alpha > 0$. By Almgren’s stratification theorem (see [10, Theorem 35.3]), for $\mathcal{H}^{m-2+\alpha}$-a.e. $x \in \text{spt}(T) \setminus \text{spt}(\partial T)$, there exists a subsequence of radii $r_k \downarrow 0$ such that $T_{x,r_k}$ converge to an integer multiplicity flat plane. Similarly, for measure-theoretic reasons, if $T$ is as in Assumption 0.4, then for $\mathcal{H}^{m-2+\alpha}$-a.e. $x \in \text{spt}(T) \setminus \text{spt}(\partial T)$ there is a subsequence $s_k \downarrow 0$ such that $\lim \inf_{k} \mathcal{H}^{m-2+\alpha}(D_{Q}(T_{x,s_k}) \cap B_1) > 0$ (see again [10]). Obviously there would then be $Q \in \mathbb{N}$ and $x \in \text{Sing}_{Q}(T)$ where both subsequences exist. The two subsequences might, however, differ: in the next proposition we show the existence of one point and a single subsequence along which both conclusions hold. For the relevant notation (concerning, for instance, excess and height of currents) we refer to [6, 4].

**Proposition 1.3** (Contradiction sequence). Under Assumption 0.4, there are $m, n, Q \geq 2$, $\Sigma$ and $T$ as in Assumption 0.1, reals $\alpha, \eta > 0$, and a sequence $r_k \downarrow 0$ such that $0 \in D_{Q}(T)$ and the following holds:

\begin{equation}
\lim_{k \to +\infty} E(T_{0,r_k}, B_{6\sqrt{m}}) = 0, \tag{1.1}
\end{equation}

\begin{equation}
\lim_{k \to +\infty} \mathcal{H}^{m-2+\alpha}(D_{Q}(T_{0,r_k}) \cap B_1) > \eta, \tag{1.2}
\end{equation}

\begin{equation}
\mathcal{H}^{m}\left((B_1 \cap \text{spt}(T_{0,r_k})) \setminus D_{Q}(T_{0,r_k})\right) > 0 \quad \forall \, k \in \mathbb{N}. \tag{1.3}
\end{equation}

The proof is based on the following lemma.

**Lemma 1.4.** Let $S$ be an $m$-dimensional area minimizing integral cone in $\mathbb{R}^{m+n}$ such that $\partial S = 0$, $Q = \Theta(S, 0) \in \mathbb{N}$, $\mathcal{H}^{m}(D_{Q}(S)) > 0$ and $\mathcal{H}^{m-1}(\text{Sing}_{Q}(S)) = 0$. Then, $S$ is an $m$-dimensional plane with multiplicity $Q$.

**Proof.** For each $x \in \text{Reg}_{Q}(S)$, let $r_x$ be such that $S \sqcup B_{2r_x}(x) = Q\lceil \Gamma \rceil$ for some regular submanifold $\Gamma$ and set

$$U := \bigcup_{x \in \text{Reg}_{Q}(S)} B_{r_x}(x).$$

Obviously, $\text{Reg}_{Q}(S) \subset U$; hence, by assumption, it is not empty. Fix $x \in \text{spt}(S) \cap \partial U$. Let next $(x_k)_{k \in \mathbb{N}} \subset \text{Reg}_{Q}(S)$ be such that $\text{dist}(x, B_{r_{x_k}}(x_k)) \to 0$. We necessarily have that $r_{x_k} \to 0$: otherwise we would have $x \in B_{2r_{x_k}}(x_k)$ for some $k$, which would imply $x \in \text{Reg}_{Q}(S) \subset U$, i.e. a contradiction. Therefore, $x_k \to x$ and, by [10, Theorem 35.1],

$$Q = \lim_{k \to +\infty} \Theta(S, x_k) \leq \Theta(S, x) = \lim_{\lambda \downarrow 0} \Theta(S, \lambda x) \leq \Theta(S, 0) = Q.$$ 

This implies $x \in D_{Q}(S)$. Since $x \in \partial U$, we must then have $x \in \text{Sing}_{Q}(S)$. Thus, we conclude that $\mathcal{H}^{m-1}(\text{spt}(S) \cap \partial U) = 0$. It follows from the standard theory of rectifiable currents (cp. Lemma A.2) that $S' := S \lceil U$ has 0 boundary in $\mathbb{R}^{m+n}$. Moreover, since $S$ is an area minimizing cone, $S'$ is also an area-minimizing cone. By definition of $U$ we have $\Theta(S', x) = Q$ for $\|S'\|$-a.e. $x$ and, by semicontinuity,

$$Q \leq \Theta(S', 0) \leq \Theta(S, 0) = Q.$$
We apply Allard’s theorem and deduce that $S'$ is regular, i.e. $S'$ is an $m$-plane with multiplicity $Q$. Finally, from $\Theta(S',0) = \Theta(S,0)$, we infer $M(S' \downarrow B_1) = M(S' \downarrow B_1)$ and then $S' = S$.

\textbf{Proof of Proposition 1.3.} Let $m > 1$ be the smallest integer for which Theorem 0.3 fails. By Almgren’s stratification theorem (cp. Theorem A.3), there must be an integer rectifiable area minimizing current $R$ of dimension $m$ and a positive integer $Q$ such that the Hausdorff dimension of $\text{Sing}_Q(R)$ is larger than $m - 2$. We fix the smallest $Q$ for which such a current $R$ exists. Recall that, by the upper semicontinuity of the density and a straightforward application of Allard’s regularity theorem (see Theorem A.1), $\text{Sing}_1(R) = \emptyset$, i.e. $Q > 1$.

Let $\alpha \in [0, 1]$ be such that $\mathcal{H}^{m-2+\alpha}(\text{Sing}_Q(R)) > 0$. By [10, Theorem 3.6] there exists a point $x \in \text{Sing}_Q(R)$ such that $\text{Sing}_Q(R)$ has positive $\mathcal{H}^{m-2+\alpha}$-upper density; i.e., assuming without loss of generality $x = 0$ and $\partial R \downarrow B_1 = 0$, there exists $r_k \downarrow 0$ such that
\[
\lim_{k \to +\infty} \mathcal{H}^{m-2+\alpha}(\text{Sing}_Q(R,0) \cap B_1) = \lim_{k \to +\infty} \frac{\mathcal{H}^{m-2+\alpha}(\text{Sing}_Q(R) \cap B_{r_k})}{r_k^{m-2+\alpha}} > 0.
\]

Up to a subsequence (not relabeled) we can assume that $R_{0,r_k} \to S$, with $S$ a tangent cone. If $S$ is a multiplicity $Q$ flat plane, then we set $T := R$ and we are done: indeed, (1.3) is satisfied by Theorem A.1, because $0 \in \text{Sing}(R)$ and $|R| \geq \mathcal{H}^m\text{L.spt}(R)$.

Assume therefore that $S$ is not an $m$-dimensional plane with multiplicity $Q$. Taking into account the convergence of the total variations for minimizing currents [10, Theorem 34.5] and the upper semicontinuity of $\mathcal{H}_\infty^{m-2+\alpha}$ under the Hausdorff convergence of compact sets, we get
\[
\mathcal{H}_\infty^{m-2+\alpha}(D_Q(S) \cap B_1) \geq \liminf_{k \to +\infty} \mathcal{H}_\infty^{m-2+\alpha}(D_Q(R_{0,r_k}) \cap B_1) > 0. \tag{1.4}
\]
We claim that (1.4) implies
\[
\mathcal{H}_\infty^{m-2+\alpha}(\text{Sing}_Q(S)) > 0. \tag{1.5}
\]
Indeed, if all points of $D_Q(S)$ are singular, then this follows from (1.4) directly. Otherwise, $\text{Reg}_Q(S)$ is not empty and, hence, $\mathcal{H}^m(D_Q(S) \cap B_1) > 0$. In this case we can apply Lemma 1.4 and infer that, since $S$ is not regular, then $\mathcal{H}^{m-1}(\text{Sing}_Q(S)) > 0$ and (1.5) holds.

We can, hence, find $x \in \text{Sing}_Q(S) \setminus \{0\}$ and $r_k \downarrow 0$ such that
\[
\lim_{k \to +\infty} \mathcal{H}_\infty^{m-2+\alpha}(\text{Sing}_Q(S \downarrow r_k) \cap B_1) = \lim_{k \to +\infty} \frac{\mathcal{H}_\infty^{m-2+\alpha}(\text{Sing}_Q(S) \cap B_{r_k}(x))}{r_k^{m-2+\alpha}} > 0.
\]
Up to a subsequence (not relabeled), we can assume that $S_{x,r_k}$ converges to $S_1$. Since $S_1$ is a tangent cone to the cone $S$ at $x \neq 0$, $S_1$ splits off a line, i.e. $S_1 = S_2 \times \mathbb{R}^n$, for some area minimizing cone $S_2$ in $\mathbb{R}^{m-1+n}$ and some $v \in \mathbb{R}^{m-n}$ (cp. the arguments in [10, Lemma 35.5]). Since $m$ is, by assumption, the smallest integer for which Theorem 0.3 fails, $\mathcal{H}^{m-3+\alpha}(\text{Sing}(S_2)) = 0$ and, hence, $\mathcal{H}^{m-2+\alpha}(\text{Sing}_Q(S_1)) = 0$. On the other hand, arguing as we did for (1.4), we have
\[
\mathcal{H}_\infty^{m-2+\alpha}(D_Q(S_1) \cap B_1) \geq \limsup_{k \to +\infty} \mathcal{H}_\infty^{m-2+\alpha}(D_Q(S_{x,r_k}) \cap B_1) > 0.
\]
Thus $\text{Reg}_Q(S_1) \neq \emptyset$ and, hence, $\mathcal{H}^m(D_Q(S_1)) > 0$. We can apply Lemma 1.4 again and conclude that $S_1$ is an $m$-dimensional plane with multiplicity $Q$. Therefore, the proposition follows taking $T := \tau_2 S$, with $\tau$ the translation map $y \mapsto y - x$, and $\Sigma$ the tangent plane at $0$ to the original Riemannian manifold.

\section{Intervals of Flattening}

For the sequel we fix the constant $c_s := \frac{1}{\alpha \sqrt{m}}$ and notice that $2^{-N_0} < c_s$, where $N_0$ is the parameter introduced in [4, Assumption 1.8]. It is always understood that the parameters $\beta_2, \delta_2, \gamma_2, \varepsilon_2, \kappa, C_e, C_h, M_0, N_0$ in [4] are fixed in such a way that all the theorems and propositions therein are applicable, cf. [4, Section 1.2]. In particular, all constants which will depend upon these parameters will be called geometric and denoted by $C_0$. On the contrary, we will highlight the dependence of the constants upon the parameters introduced in this paper $p_1, p_2, \ldots$ by writing $C = C(p_1, p_2, \ldots)$.

We recall also the notation introduced in [4, Assumption 1.3]. If $\Sigma \cap B_{7\sqrt{m}}$ has no boundary in $B_{7\sqrt{m}}$ and for any $p \in \Sigma \cap B_{7\sqrt{m}}$ there is a map $\Psi_p : T_p \Sigma \supset \Omega \rightarrow (T_p \Sigma)^\perp$ parametrizing it, then $c(\Sigma \cap B_{7\sqrt{m}}) := \sup_{p \in \Sigma \cap B_{7\sqrt{m}}} \|D\Psi_p\|_{C^{0,\alpha}}$. Obviously these assumptions might fail for a general $\Sigma$ (in fact $c(\Sigma \cap B_{7\sqrt{m}})$ need not be well-defined). However, having fixed a point $q \in \Sigma$, given its $C^{0,\alpha}$ regularity, $c(\iota_{q, r}(\Sigma) \cap B_{7\sqrt{m}})$ is well-defined whenever $r$ is sufficiently small and converges to 0 as $r \downarrow 0$. In particular, by Proposition 1.3 and simple rescaling arguments, we assume in the sequel the following.

\textbf{Assumption 2.1.} Let $\varepsilon_3 \in ]0, \varepsilon_2[$. Under Assumption 0.4, there exist $m, n, Q \geq 2$, $\alpha, \eta > 0$, $T$ and $\Sigma$ for which:

(a) there is a sequence of radii $r_k \downarrow 0$ as in Proposition 1.3;

(b) the following holds:

\begin{align}
T_0 \Sigma &= \mathbb{R}^{m+n} \times \{0\}, \quad \text{spt}(\partial T) \cap B_{6\sqrt{m}} = \emptyset, \quad 0 \in D_Q(T), \quad (2.1) \\
\|T\|(B_{6\sqrt{m}}) &\leq r^m \left( Q \omega_m(6\sqrt{m})^m + \varepsilon_3^2 \right) \quad \text{for all } r \in (0, 1), \quad (2.2) \\
c(\Sigma \cap B_{7\sqrt{m}}) &\leq \varepsilon_3. \quad (2.3)
\end{align}

\subsection{Defining procedure.}

We set

$$\mathcal{R} := \{ r \in ]0, 1] : E(T, B_{6\sqrt{m}}) \leq \varepsilon_3^2 \}.$$ (2.4)

Observe that, if $\{s_k\} \subset \mathcal{R}$ and $s_k \uparrow s$, then $s \in \mathcal{R}$. We cover $\mathcal{R}$ with a collection $\mathcal{F} = \{I_j\}_j$ of intervals $I_j = [s_j, t_j]$ defined as follows. $t_0 := \max\{t : t \in \mathcal{R}\}$. Next assume, by induction, to have defined $t_j$ (and hence also $t_0 > s_0 \geq t_1 > s_1 \geq \ldots > s_{j-1} \geq t_j$) and consider the following objects:

- $T_j := ((t_0, t_j) T) \cup B_{6\sqrt{m}}$, $\Sigma_j := (t_0, t_j) (\Sigma) \cap B_{7\sqrt{m}}$; moreover, consider for each $j$ an orthonormal system of coordinates so that, if we denote by $\pi_0$ the $m$-plane $\mathbb{R}^m \times \{0\}$, then $E(T_j, B_{6\sqrt{m}}, \pi_0) = E(T_j, B_{6\sqrt{m}})$ (alternatively we can keep the system of coordinates fixed and rotate the currents $T_j$).
- Let \( \mathcal{M}_j \) be the corresponding center manifold constructed in [4, Theorem 1.17] applied to \( T_j \) and \( \Sigma_j \) with respect to the \( m \)-plane \( \pi_0 \); the manifold \( \mathcal{M}_j \) is then the graph of a map \( \varphi_j : \pi_0 \supset [-4, 4]^m \rightarrow \pi_0^+ \), and we set \( \Phi_j(x) := (x, \varphi_j(x)) \in \pi_0 \times \pi_0^+ \).

Then,

(Stop) either there is \( r \in ]0, 3[ \) and a cube \( L \) of the Whitney decomposition \( \mathcal{W}^{(j)} \) of \( [-4, 4]^m \subset \pi_0 \) of [4, Definition 1.10 & Proposition 1.11] (applied to \( T_j \)) s.t.

\[
\ell(L) \geq c_s r \quad \text{and} \quad L \cap \bar{B}_r(0, \pi_0) \neq \emptyset \tag{2.5}
\]

(in what follows \( B_r(p, \pi) \) and \( \bar{B}_r(p, \pi) \) will denote the open and closed disks \( B_r(p) \cap (p + \pi), \bar{B}_r(p) \cap (p + \pi) \));

(Go) or there exists no radius as in (Stop).

We will prove below that, if \( r \) is as in (Stop), then \( r < 2^{-5} \). This justifies the following: in case (Go) holds, we set \( s_j := 0 \), i.e. \( I_j := ]0, t_j[ \), and end the procedure; in case (Stop) holds we let \( s_j := \bar{r} t_j \), where \( \bar{r} \) is the maximum radius satisfying (Stop). We choose then \( t_{j+1} \) as the largest element in \( \mathcal{R} \cap ]0, s_j[ \) and proceed inductively.

2.2. First consequences. The following is a list of easy consequences of the definition. Given two sets \( A \) and \( B \), we define their separation as the number \( \text{sep}(A, B) := \inf \{|x - y| : x \in A, y \in B\} \).

**Proposition 2.2.** Assuming \( \varepsilon_3 \) sufficiently small, then the following holds:

(i) \( s_j < t_j^2 \) and the family \( \mathcal{F} \) is either countable and \( t_j \downarrow 0 \), or finite and \( I_j = ]0, t_j[ \) for the largest \( j \);

(ii) the union of the intervals of \( \mathcal{F} \) cover \( \mathcal{R} \), and for \( k \) large enough the radii \( r_k \) in Assumption 2.1 belong to \( \mathcal{R} \);

(iii) if \( r \in ]\frac{3}{t_j}, 3[ \) and \( J \in \mathcal{W}^{(j)} \) intersects \( B := p_{\pi_0}(B_r(p_j)) \), with \( p_j := \Phi_j(0) \), then \( J \) is in the domain of influence \( \mathcal{W}^{(j)}_\ell(H) \) (see [4, Definition 3.3]) of a cube \( H \in \mathcal{W}^{(j)}_\ell \) with

\[
\ell(H) \leq 3 c_s r \quad \text{and} \quad \max \{\text{sep}(H, B), \text{sep}(H, J)\} \leq 3 \sqrt{m} \ell(H) \leq \frac{3r}{16};
\]

(iv) \( E(T_j, B_r) \leq C_0 r^2 2^{-2\beta_2} \) for every \( r \in ]\frac{3}{t_j}, 3[ \).

(v) \( \sup\{\text{dist}(x, \mathcal{M}_j) : x \in \text{spt}(T_j) \cap p_j^{-1}(B_r(p_j))\} \leq C_0 (m_j^0)^{\frac{1}{p_m}} r^{1+\beta_2} \) for every \( r \in ]\frac{s_j}{t_j}, 3[ \), where \( m_j^0 := \max\{c(\Sigma_j)^2, E(T_j, B_{6\sqrt{m_j^0}})\} \).

**Proof.** We start by noticing that \( s_j < t_j^2 \) follows from the inequality \( 2^{-N_0 - 1} < c_s \) (cf. [4, Assumption 1.8]) because all cubes in the Whitney decomposition have side-length at most \( 2^{-N_0 - 6} \) (cf. [4, Proposition 1.11]). In particular, this implies that the inductive procedure either never stops, leading to \( t_j \downarrow 0 \), or it stops because \( s_j = 0 \) and \( ]0, t_j[ \subset \mathcal{R} \), thus proving (i). The first part of (ii) follows straightforwardly from the choice of \( t_{j+1} \), and the last assertion holds from \( E(T, B_{6\sqrt{m_j^0}}) \rightarrow 0 \).
Regarding (iii), let \( H \in \mathcal{W}_{(j)} \) be as in [4, Definition 3.3] and choose \( k \in \mathbb{N} \setminus \{0\} \) such that \( \ell(H) = 2^k \ell(J) \). Observe that \( \|D\varphi_j\|_{C^{1,\varepsilon}} \leq C_0\varepsilon_3 \) by [4, Theorem 1.17]. If \( \varepsilon_3 \) is sufficiently small, we can assume
\[
B_{r/2}(0, \pi_0) \subset B \subset B_r(0, \pi_0).
\]
Now, by [4, Corollary 3.2], \( \text{sep}(H, J) \leq 2\sqrt{m}\ell(H) \) and
\[
\text{sep}(B, H) \leq \text{sep}(H, J) + 2\sqrt{m}\ell(J) \leq 3\sqrt{m}\ell(H).
\]
Both the inequalities claimed in (iii) are then trivial when \( r > 1/4 \), because \( \ell(H) \leq 2^{-N_0 - 6} \leq 2^{-5}c_s \leq 2^{-9}/\sqrt{m} \). Assume therefore \( r \leq 1/4 \) and note that \( H \) intersects \( B_{2r + 3\sqrt{m}\ell(H)} \). Let \( \rho := 2r + 3\sqrt{m}\ell(H) \). Observe that \( 2r < \rho < 1 \). Since for such \( \rho \) (Stop) cannot hold, we have that
\[
\ell(H) < c_s (2r + 3\sqrt{m}\ell(H)) = 2c_s r + \frac{3\ell(H)}{16}.
\]
Therefore, we conclude that \( \ell(H) \leq 3c_s r \) and \( \text{sep}(H, B) \leq 9\sqrt{m}c_s r < 3r/16 \).

We now turn to (iv). If \( r \geq 2^{-N_0} \), then obviously
\[
E(T_j, B_r) \leq (4\sqrt{m}2^{N_0})^{m+2 - 2k}2^{2 - 2k}E(T_j, B_{1/\sqrt{m}}) \leq (4\sqrt{m}2^{N_0})^{m+2 - 2k}2^{2 - 2k}\varepsilon_3^2.
\]
Otherwise, let \( k \geq N_0 \) be the smallest natural number such that \( 2^{-k+1} > r \) and let \( L \in \mathcal{W}_{(j),k} \cup \mathcal{F}_{(j),k} \) be a cube so that \( 0 \in L \) (cf. [4, Definition 1.10], \( \ell(H) = 2^{-k} \)). By [4, Proposition 4.2(v)], \( |p_L| \leq (\sqrt{m} + C_0(m_j^d)^{1/2m}) \leq 2\sqrt{m}\ell(H) \) and so it follows easily that \( B_r \subset B_L \). From condition (Go) we have \( L \notin \mathcal{W}_{(j)} \). Thus, by [4, Proposition 1.11], we get
\[
E(T_j, B_r) \leq C_0E(T_j, B_L) \leq C_0\varepsilon_3^2 r^{2 - 2k}.
\]
Finally, (v) follows from [4, Corollary 2.2 (ii)], because by (Go), for every \( r \in ]t_j/4, 3[ \), every cube \( L \in \mathcal{W}_{(j)} \) which intersects \( B_r(0, \pi_0) \) satisfies \( \ell(L) < c_s r \).

3. Frequency function and first variations

Consider the following Lipschitz (piecewise linear) function \( \phi : [0 + \infty \rightarrow [0, 1] \) given by
\[
\phi(r) := \begin{cases} 
1 & \text{for } r \in [0, \frac{1}{2}], \\
2 - 2r & \text{for } r \in ]\frac{1}{2}, 1[, \\
0 & \text{for } r \in ]1, +\infty[.
\end{cases}
\]

For every interval of flattening \( I_j = ]s_j, t_j[ \), let \( N_j \) be the normal approximation of \( T_j \) on \( \mathcal{M}_j \) in [4, Theorem 2.4].

**Definition 3.1** (Frequency functions). For every \( r \in ]0, 3] \) we define:
\[
D_j(r) := \int_{\mathcal{M}_j} \phi \left( \frac{d_j(p)}{r} \right) |DN_j|^2(p) \, dp \quad \text{and} \quad H_j(r) := -\int_{\mathcal{M}_j} \phi' \left( \frac{d_j(p)}{r} \right) \frac{|N_j|^2(p)}{d(p)} \, dp,
\]
where \( d_j(p) \) is the geodesic distance on \( \mathcal{M}_j \) between \( p \) and \( \Phi_j(0) \). If \( H_j(r) > 0 \), we define the *frequency function* \( \mathbf{I}_j(r) := \frac{rD_j(r)}{H_j(r)} \).
The following is the main analytical estimate of the paper, which allows us to exclude infinite order of contact among the different sheets of a minimizing current.

**Theorem 3.2** (Main frequency estimate). If $\varepsilon_3$ is sufficiently small, then there exists a geometric constant $C_0$ such that, for every $[a, b] \subset \left[\frac{\varepsilon_3}{\gamma_3}, 3\right]$ with $H_j|_{[a, b]} > 0$, we have

$$I_j(a) \leq C_0(1 + I_j(b)).$$

To simplify the notation, in this section we drop the index $j$ and omit the measure $\mathcal{H}^m$ in the integrals over regions of $\mathcal{M}$. The proof exploits four identities collected in Proposition 3.5, which will be proved in the next sections.

**Definition 3.3.** We let $\partial_r$ denote the derivative with respect to arclength along geodesics starting at $\Phi(0)$. We set

$$E(r) := -\int_{\mathcal{M}} \phi' \left( \frac{d(p)}{r} \right) \sum_{i=1}^{Q} \langle N_i(p), \partial_r N_i(p) \rangle \, dp,$$

$$G(r) := -\int_{\mathcal{M}} \phi' \left( \frac{d(p)}{r} \right) d(p) |\partial_r N(p)|^2 \, dp \quad \text{and} \quad \Sigma(r) := \int_{\mathcal{M}} \phi \left( \frac{d(p)}{r} \right) |N|^2(p) \, dp.$$  

**Remark 3.4.** Observe that all these functions of $r$ are absolutely continuous and, therefore, classically differentiable at almost every $r$. Moreover, the following rough estimate easily follows from [4, Theorem 2.4] and the condition (Stop):

$$D(r) \leq C_0 m_0 r^{m+2-2\delta_3} \quad \text{for every} \quad r \in \left[\frac{\varepsilon_3}{3}, 3\right].$$

Indeed, since $N$ vanishes identically on the set $\mathcal{K}$ of [4, Theorem 2.4], it suffices to sum the estimate of [4, Theorem 2.4, (2.3)] over all the different cubes $L$ (of the corresponding Whitney decomposition) for which $\Phi(L)$ intersects the geodesic ball $B_r$.

**Proposition 3.5** (First variation estimates). For every $\gamma_3$ sufficiently small there is a constant $C = C(\gamma_3) > 0$ such that, if $\varepsilon_3$ is sufficiently small, $[a, b] \subset \left[\frac{\varepsilon_3}{3}, 3\right]$ and $I \geq 1$ on $[a, b]$, then the following inequalities hold for a.e. $r \in [a, b]$:

$$|H'(r) - \frac{m-1}{r} H(r) - \frac{2}{r} E(r)| \leq CH(r),$$

$$D(r) - r^{-1} E(r) \leq CD(r)^{1+\gamma_3} + C \varepsilon_3^2 \Sigma(r),$$

$$|D'(r) - \frac{m-2}{r} D(r) - \frac{2}{r^2} G(r)| \leq CD(r) + CD(r)^{\gamma_3} D'(r) + C r^{-1} D(r)^{1+\gamma_3},$$

$$\Sigma(r) + r \Sigma'(r) \leq C r^2 D(r) \leq C r^{2+m} \varepsilon_3^2.$$

We assume for the moment the proposition and prove the theorem.

**Proof of Theorem 3.2.** Set $\Omega(r) := \log \left\{ \max \{I(r), 1\} \right\}$. Fix a $\gamma_3 > 0$ and an $\varepsilon_3$ sufficiently small so that the conclusion of Proposition 3.5. We can thus treat the corresponding constants in the inequalities as geometric ones, but to simplify the notation we keep denoting them by $C$.

To prove (3.1) it is enough to show $\Omega(a) \leq C + \Omega(b)$. If $\Omega(a) = 0$, then there is nothing to prove. If $\Omega(a) > 0$, let $b' \in [a, b]$ be the supremum of $t$ such that $\Omega > 0$ on $[a, t[$. If
$b < b'$, then $\Omega(b') = 0 \leq \Omega(b)$. Therefore, by possibly substituting $|a, b|$ with $|a, b'|$, we can assume that $\Omega > 0$, i.e. $I > 1$, on $|a, b|$. By Proposition 3.5, if $\varepsilon_3$ is sufficiently small, then

$$\frac{D(r)}{2} \leq \frac{E(r)}{r} \leq 2D(r), \quad \text{(3.9)}$$

from which we conclude that $E > 0$ over the interval $|a, b'|$. Set for simplicity $F(r) := D(r)^{-1} - rE(r)^{-1}$, and compute

$$-\Omega'(r) = \frac{H'(r)}{H(r)} - \frac{D'(r)}{D(r)} - \frac{1}{r}, \quad \text{where} \quad D(r) \frac{H'(r)}{H(r)} - \frac{rD'(r)}{E(r)} - \frac{D'(r)F(r)}{r} - \frac{1}{r}.$$

Again by Proposition 3.5:

$$\frac{H'(r)}{H(r)} \leq \frac{m - 1}{r} + C \frac{E(r)}{rH(r)}, \quad \text{(3.10)}$$

$$|F(r)| \leq C \frac{r(D(r)^{1+\gamma_3} + \Sigma(r))}{D(r)E(r)} \leq C \frac{D(r)^{\gamma_3 - 1} + C \Sigma(r)}{D(r)^2}, \quad \text{(3.11)}$$

$$-\frac{rD'(r)}{E(r)} \leq \left( C - \frac{m - 2}{r} \right) \frac{rD(r)}{E(r)} - \frac{2}{r} \frac{G(r)}{E(r)} + C \frac{rD(r)^{\gamma_3} D'(r) + D(r)^{1+\gamma_3}}{E(r)} \leq C - \frac{m - 2}{r} + C \frac{D(r)F(r)}{E(r)} - \frac{2}{r} \frac{G(r)}{E(r)} + C \frac{D(r)^{\gamma_3} D'(r) + C \Sigma(r)}{D(r)^2} \leq C - \frac{m - 2}{r} + \frac{2}{r} \frac{G(r)}{E(r)} + C \frac{D(r)^{\gamma_3} D'(r) + C \Sigma(r)}{D(r)^2}. \quad \text{(3.12)}$$

By Cauchy-Schwartz, we have

$$\frac{E(r)}{rH(r)} \leq \frac{G(r)}{rE(r)}. \quad \text{(3.13)}$$

Thus, by (3.4), (3.10), (3.12) and (3.13), we conclude

$$-\Omega'(r) \leq C + C r^{\gamma_3 m - 1} + C rD(r)^{\gamma_3 - 1} F'(r) - D'(r)F(r) \leq C r^{\gamma_3 m - 1} + C D(r)^{\gamma_3 - 1} F'(r) + C \frac{\Sigma(r)D'(r)}{D(r)^2}. \quad \text{(3.14)}$$

Integrating (3.14) we conclude:

$$\Omega(a) - \Omega(b) \leq C + C \left( D(b)^{\gamma_3} - D(a)^{\gamma_3} \right) + C \left[ \frac{\Sigma(a)}{D(a)} - \frac{\Sigma(b)}{D(b)} + \int_a^b \frac{\Sigma'(r)}{D(r)} dr \right] \leq C. \quad \blacksquare$$

The rest of the section is devoted to the proof of Proposition 3.5.
3.1. Estimates on $H'$: proof of (3.5). Set $q := \Phi(0)$. Let $\exp : B_3 \subset T_q \mathcal{M} \to \mathcal{M}$ be the exponential map and $J$ $\exp$ its Jacobian. Note that $d(\exp(y), q) = |y|$ for every $y \in B_3$. By the area formula, setting $y = rz$, we can write $H$ in the following way:

$$H(r) = -r^{m-1} \int_{T_q \mathcal{M}} \frac{\phi'(|z|)}{|z|} |N|^2(\exp(rz)) J \exp(rz) \, dx.$$ 

Therefore, differentiating under the integral sign, we easily get (3.5):

$$H'(r) = -(m-1) r^{m-2} \int_{T_q \mathcal{M}} \frac{\phi'(|z|)}{|z|} |N|^2(\exp(rz)) J \exp(rz) \, dz$$

$$- 2 r^{m-1} \int_{T_q \mathcal{M}} \phi'(|z|) \sum_i \left< N_i(\exp(rz)), \partial_r N_i(\exp(rz)) \right> J \exp(rz) \, dz$$

$$- r^{m-1} \int_{T_q \mathcal{M}} \frac{\phi'(|z|)}{|z|} |N|^2(\exp(rz)) \frac{d}{dr} J \exp(rz) \, dz$$

$$= \frac{m-1}{r} H(r) + \frac{2}{r} E(r) + O(1) H(r),$$

where we used that $\frac{d}{dr} J \exp(rz) = O(1)$, because $\mathcal{M}$ is a $C^{3,\kappa}$ submanifold and hence $\exp$ is a $C^{2,\kappa}$ map (see Proposition A.4).

3.2. $\Sigma$ and $\Sigma'$: proof of (3.8). We show the following more precise estimates.

Lemma 3.6. There exists a dimensional constant $C_0 > 0$ such that

$$\Sigma(r) \leq C_0 r^2 D(r) + C_0 r H(r) \quad \text{and} \quad \Sigma'(r) \leq C_0 H(r), \quad (3.15)$$

$$\int_{B_r(q)} |N|^2 \leq C_0 \Sigma(r) + C_0 r H(r), \quad (3.16)$$

$$\int_{B_r(q)} |DN|^2 \leq C_0 D(r) + C_0 r D'(r). \quad (3.17)$$

In particular, if $I \geq 1$, then (3.8) holds and

$$\int_{B_r(q)} |N|^2 \leq C_0 r^2 D(r). \quad (3.18)$$

Proof. To simplify the notation we drop the subscript $\theta$ from the geometric constants. Observe that $\psi(p) := \phi(\frac{d(p)}{r}) |N|^2(p)$ is a Lipschitz function with compact support in $B_r(q)$. We therefore use the Poincaré inequality: $\Sigma(r) = \int_{\mathcal{M}} \psi \leq C r \int_{\mathcal{M}} |D\psi|$ (the constant $C$ depends on the smoothness of $\mathcal{M}$). We compute

$$\Sigma(r) \leq -C \int_{\mathcal{M}} \phi'(r^{-1} d(p)) |N|^2(p) + C r \int_{\mathcal{M}} \phi(r^{-1} d(p)) |N||DN|$$

$$\leq C r H(r) + C \Sigma(r)^{1/2} (r^2 D(r))^{1/2} \leq C r H(r) + \frac{1}{2} \Sigma(r) + C r^2 D(r),$$
which gives the first part of (3.15). The remaining inequality is straightforward:

$$\Sigma'(r) = - \int_M \frac{d(p)}{r^2} \phi' \left( \frac{d(p)}{r} \right) |N|^2(p) \leq C H(r).$$

Since $\phi' = 0$ on $]0, \frac{1}{2}[$ and $\phi' = -2$ on $\frac{1}{2}, 1[$, we easily deduce

$$\int_{B_r(q) \setminus B_{r/2}(q)} |N|^2 \leq r H(r),$$

$$r D'(r) = - \int_M \frac{d(p)}{r} \phi' \left( \frac{d(p)}{r} \right) |DN|^2 \geq \int_{B_r(q) \setminus B_{r/2}(q)} |DN|^2.$$

On the other hand, since $\phi = 1$ on $]0, \frac{1}{2}[$, (3.16) and (3.17) readily follow. Therefore, in the hypothesis $I \geq 1$, i.e. $H \leq r D$, we conclude (3.8) from (3.15).

3.3. First variations. To prove the remaining estimates in Proposition 3.5 we exploit the first variation of $T$ along some vector fields $X$. The variations are denoted by $\delta T(X)$. We fix a neighborhood $U$ of $M$ and the normal projection $p : U \to M$ as in [4, Assumption 2.1]. Observe that $p \in C^2, \kappa$ and [5, Assumption 3.1] holds. We will consider:

- the outer variations, where $X_p = X_o(p) := \phi \left( \frac{d(p)}{r} \right) (p - p(p))$,
- the inner variations, where $X_p = X_i(p) := Y(p(p))$ with

$$Y(p) := \frac{d(p)}{r} \phi \left( \frac{d(p)}{r} \right) \frac{\partial}{\partial r} \forall p \in M$$

($\frac{\partial}{\partial r}$ is the unit vector field tangent to the geodesics emanating from $\Phi(0)$ and pointing outwards).

Note that $X_i$ is the infinitesimal generator of a one parameter family of bilipschitz homeomorphisms $\Phi$, defined as $\Phi_i := \Psi_i(p(p)) + p - p(p)$, where $\Psi_i$ is the one-parameter family of bilipschitz homeomorphisms of $M$ generated by $Y$.

Consider now the map $F(p) := \sum_i \left[ p + N_i(p) \right]$ and the current $T_F$ associated to its image (cf. [5] for the notation). Observe that $X_i$ and $X_o$ are supported in $p^{-1}(B_r(q))$ but none of them is compactly supported. However, recalling Proposition 2.2 (v) and the minimizing property of $T$ in $\Sigma$, we deduce that $\delta T(X) = \delta T(X^T) + \delta T(X^\perp) = \delta T(X^\perp)$, where $X = X^T + X^\perp$ is the decomposition of $X$ in the tangent and normal components to $T\Sigma$. Then, we have

$$|\delta T_F(X)| \leq |\delta T_F(X) - \delta T(X)| + |\delta T(X^\perp)|$$

$$\leq \int_{spt(T) \setminus \text{Im}(F)} |\text{div}_F X| \ d\|T\| + \int_{\text{Im}(F) \setminus spt(T)} |\text{div}_{\overline{T}_F} X| \ d\|T\| + \int_{\text{Err}_4} |\text{div}_{\overline{T}_F} X^\perp| \ d\|T\| + \int_{\text{Err}_5} |\text{div}_{\overline{T}_F} X^\perp| \ d\|T\|. \tag{3.19}$$
Set now for simplicity $\varphi_r(p) := \phi\left(\frac{d(p)}{r}\right)$. We wish to apply [5, Theorem 4.2] to conclude

$$
\delta T_F(X_o) = \int_M \left( \varphi_r |DN|^2 + \sum_{i=1}^Q N_i \otimes \nabla \varphi_r : DN_i + \sum_{j=1}^3 \text{Err}_j^o \right),
$$

where the errors $\text{Err}_j^o$ correspond to the terms $\text{Err}_j$ of [5, Theorem 4.2]. This would imply

$$
\text{Err}_1^o = -Q \int_M \varphi_r \langle H_M, \eta \circ N \rangle, \quad (3.21)
$$

$$
|\text{Err}_2^o| \leq C_0 \int_M |\varphi_r| |A|^2 |N|^2, \quad (3.22)
$$

$$
|\text{Err}_3^o| \leq C_0 \int_M \left( |N| |A| + |DN|^2 \right) \left( |\varphi_r| |DN|^2 + |D\varphi_r| |DN| |N| \right), \quad (3.23)
$$

where $H_M$ is the mean curvature vector of $M$. Note that [5, Theorem 4.2] requires the $C^1$ regularity of $\varphi_r$. We overcome this technical obstruction applying [5, Theorem 4.2] to a standard smoothing of $\varphi$ and then passing into the limit (the obvious details are left to the reader). Plugging (3.20) into (3.19), we then conclude

$$
|D(r) - r^{-1}E(r)| \leq \sum_{j=1}^5 |\text{Err}_j^o|, \quad (3.24)
$$

where $\text{Err}_4^o$ and $\text{Err}_5^o$ correspond respectively to $\text{Err}_4$ and $\text{Err}_5$ of (3.19) when $X = X_o$. With the same argument, but applying this time [5, Theorem 4.3] to $X = X_i$, we get

$$
\delta T_F(X_i) = \frac{1}{2} \int_M \left( |DN|^2 \text{div}_M Y - 2 \sum_{i=1}^Q \langle DN_i : (DN_i \cdot D_M Y) \rangle \right) + \sum_{j=1}^3 \text{Err}_j^i, \quad (3.25)
$$

where this time the errors $\text{Err}_j^i$ correspond to the error terms $\text{Err}_j$ of [5, Theorem 4.3], i.e.

$$
\text{Err}_1^i = -Q \int_M \left( \langle H_M, \eta \circ N \rangle \text{div}_M Y + \langle D_Y H_M, \eta \circ N \rangle \right), \quad (3.26)
$$

$$
|\text{Err}_2^i| \leq C_0 \int_M |A|^2 \left( |DY||N|^2 + |Y||N||DN| \right), \quad (3.27)
$$

$$
|\text{Err}_3^i| \leq C_0 \int_M \left( |Y||A||DN|^2 \left( |N| + |DN| \right) + |DY||A||N|^2 |DN| + |DN|^4 \right). \quad (3.28)
$$

Straightforward computations (again appealing to Proposition A.4) lead to

$$
D_M Y(p) = \phi' \left( \frac{d(p)}{r} \right) \frac{d(p)}{r^2} \otimes \frac{\partial}{\partial r} + \phi \left( \frac{d(p)}{r} \right) \left( \frac{\text{Id}}{r} + O(1) \right), \quad (3.29)
$$

$$
\text{div}_M Y(p) = \phi' \left( \frac{d(p)}{r} \right) \frac{d(p)}{r^2} + \phi \left( \frac{d(p)}{r} \right) \left( \frac{m}{r} + O(1) \right). \quad (3.30)
$$
Plugging (3.29) and (3.30) into (3.25) and using (3.19) we then conclude

$$\left| D'(r) - (m - 2)r^{-3}D(r) - 2r^{-2}G(r) \right| \leq C_6D(r) + \sum_{j=1}^{5} \left| \text{Err}_j \right| .$$

(3.31)

Proposition 3.5 is then proved by the estimates of the errors terms done in the next section.

4. Error estimates

We start with some preliminary considerations, keeping the notation and convention of the previous section (and dropping the subscript when dealing with the maps of Theorem 3.2 and Proposition 3.5).

4.1. Families of subregions. Set \( q := \Phi(0) \). We select a family of subregions of \( B_r(p) \subset \mathcal{M} \). Denote by \( B \) and \( \partial B \) respectively \( p(B_r(q)) \) and \( p(\partial B_r(q)) \), where \( \pi \) is the reference \( m \)-dimensional plane of the construction of the center manifold \( \mathcal{M} \). Since \( ||\phi||_{C^{3,\alpha}} \leq C \varepsilon^{1/m} \) (cf. [4, Theorem 1.17]), by Proposition A.4 we can assume that \( B \) is a \( C^2 \) convex set which at any boundary point \( p \) contains an interior sphere of radius \( r/2 \) passing through \( p \). Thus:

\[ \forall z \in \partial B \quad \text{there is a ball } B_{r/2}(y, \pi) \subset B \text{ whose closure touches } \partial B \text{ at } z. \] (4.1)

**Definition 4.1** (Family of cubes). We first define a family \( \mathcal{T} \) of cubes in the Whitney decomposition \( \mathcal{W} \) as follows:

(i) \( \mathcal{T} \) includes all \( L \in \mathcal{W}_n \cup \mathcal{W}_c \) which intersect \( B \);

(ii) if \( L' \in \mathcal{W}_n \) intersects \( B \) and belongs to the domain of influence \( \mathcal{W}_n(L) \) of the cube \( L \in \mathcal{W}_c \) as in [4, Corollary 3.2], then \( L \in \mathcal{T} \).

**Definition 4.2** (Associated balls \( B^L \)). By Proposition 2.2 (iii), \( \ell(L) \leq 3c_\alpha r \leq r \) and \( \text{sep}(L,B) \leq 3\sqrt{m} \ell(L) \) for each \( L \in \mathcal{T} \). Let \( x_L \) be the center of \( L \) and:

(a) if \( x_L \in \overline{B} \), we then set \( s(L) := \ell(L) \) and \( B^L := B_{s(L)}(x_L, \pi) \);

(b) otherwise we consider the ball \( B_{\ell(L)}(x_L, \pi) \subset \partial B \) at exactly one point \( p(L) \), we set \( s(L) := r(L) + \ell(L) \) and define \( B^L := B_{s(L)}(x_L, \pi) \).

We proceed to select a countable family \( \mathcal{F} \) of pairwise disjoint balls \( \{B^L\} \). We let \( S := \sup_{L \in \mathcal{T}} s(L) \) and start selecting a maximal subcollection \( \mathcal{T}_1 \) of pairwise disjoint balls with radii larger than \( S/2 \). Clearly, \( \mathcal{T}_1 \) is finite. In general, at the stage \( k \), we select a maximal subcollection \( \mathcal{T}_k \) of pairwise disjoint balls which do not intersect any of the previously selected balls in \( \mathcal{T}_1 \cup \ldots \cup \mathcal{T}_{k-1} \) and which have radii \( r \in [2^{-k}S, 2^{1-k}S] \). Finally, we set \( \mathcal{F} := \bigcup_k \mathcal{T}_k \).

**Definition 4.3** (Family of cube-ball pairs \( (L, B(L)) \in \mathcal{F} \)). Recalling (4.1) and \( \ell(L) \leq r \), it easy to see that there exist balls \( B_{\ell(L)/4}(ql, \pi) \subset B^L \cap B \) which lie at distance at least \( \ell(L)/4 \) from \( \partial B \). We denote by \( B(L) \) one such ball and by \( \mathcal{F} \) the collection of pairs \( (L, B(L)) \) with \( B^L \in \mathcal{F} \).
Next, we partition the cubes of $\mathcal{W}$ which intersect $B$ into disjoint families $\mathcal{W}(L)$ labeled by $(L,B(L)) \in \mathcal{Z}$ in the following way (observe that $\mathcal{W}(L)$ and $\mathcal{W}_e(L)$ are different families and should not be confused!). Let $H \in \mathcal{W}$ have nonempty intersection with $B$. If $H$ is itself in $\mathcal{T}$, we then select $L \in \mathcal{T}$ with $B^L \cap B^H \neq \emptyset$ and assign $H \in \mathcal{W}(L)$. Otherwise $H$ is in the domain of influence of some $J \in \mathcal{W}_e$. By Proposition 2.2, the separation between $J$ and $H$ is at most $3\sqrt{m\ell}(J)$ and, hence, $H \subset B_{4\sqrt{m\ell}(J)}(x_J)$. By construction there is a $B^L \in \mathcal{T}$ with $B^L \cap B^H \neq \emptyset$ and radius $s(L) \geq \frac{s(J)}{2}$. We then prescribe $H \in \mathcal{W}(L)$. Observe that $s(L) \leq 4\sqrt{m\ell}(L)$ and $s(J) \geq \ell(J)$. Therefore, $\ell(J) \leq 8\sqrt{m\ell}(L)$ and $|x_J - x_L| \leq 5s(L) \leq 20\sqrt{m\ell}(L)$. This implies that

$$H \subset B_{4\sqrt{m\ell}(J)}(x_J) \subset B_{4\sqrt{m\ell}(J)+20\sqrt{m\ell}(L)}(x_L) \subset B_{30\sqrt{m\ell}(L)}(x_L).$$

The inclusion $H \subset B_{30\sqrt{m\ell}(L)}(x_L)$ holds also in case $H \in \mathcal{T}$, as can be easily seen simply setting $J = H$ and using the same computations. For later reference, we collect the main properties of the above construction.

**Lemma 4.4.** The following holds.

(i) If $(L,B(L)) \in \mathcal{Z}$, then $L \in \mathcal{W}_e \cup \mathcal{W}_h$, the radius of $B(L)$ is $\frac{\ell(L)}{4}$, $B(L) \subset B^L \cap B$ and separation $(B(L), \partial B) \geq \frac{\ell(L)}{4}$.

(ii) If the pairs $(L,B(L)), (L',B(L')) \in \mathcal{Z}$ are distinct, then $L$ and $L'$ are distinct and $B(L) \cap B(L') = \emptyset$.

(iii) The cubes $\mathcal{W}$ which intersect $B$ are partitioned into disjoint families $\mathcal{W}(L)$ labeled by $(L,B(L)) \in \mathcal{Z}$ such that, if $H \in \mathcal{W}(L)$, then $H \subset B_{30\sqrt{m\ell}(L)}(x_L)$.

### 4.2. Basic estimates in the subregions.

For notational convenience, we order the family $\mathcal{Z} = \{(L_i,B(L_i))\}_{i \in \mathbb{N}}$, and set

$$\mathcal{B}^i := \Phi(B(L_i)), \quad \mathcal{U}_i = \cup_{H \in \mathcal{W}(L_i)} \Phi(H) \cap \mathcal{B}_r(q)$$

(recall that $q = \Phi(0)$). Observe that the separation between $\mathcal{B}^i$ and $\partial \mathcal{B}_r(q)$ is larger than that between $B(L_i)$ and $\partial B = \mathcal{B}_r(\partial \mathcal{B}_r(q))$. Thus, by Lemma 4.4 (i), $\varphi_r(p) = \phi\left(\frac{d(p)}{r}\right)$ satisfies

$$\inf_{p \in \mathcal{B}^i} \varphi_r(p) \geq (4r)^{-1}\ell_i, \quad (4.2)$$

where $\ell_i := \ell(L_i)$. From this and Lemma 4.4 (iii), we also obtain

$$\sup_{p \in \mathcal{U}_i} \varphi_r(p) - \inf_{p \in \mathcal{U}_i} \varphi_r(p) \leq C \operatorname{Lip}(\varphi_r) \ell_i \leq \frac{C}{r} \ell_i \leq C \inf_{p \in \mathcal{B}^i} \varphi_r(p), \quad (4.2)$$

which translates into

$$\sup_{p \in \mathcal{U}_i} \varphi_r(p) \leq C \inf_{p \in \mathcal{B}^i} \varphi_r(p). \quad (4.3)$$
Moreover, set \( V_i := U_i \setminus K \), where \( K \) is the coincidence set of \([4, \text{Theorem 2.4}]\). From \([4, \text{Theorem 2.4}]\), we derive the following estimates:

\[
\int_{U_i} |\eta \circ N| \leq C_0 m_0 \ell_i^{2+m+\gamma_2/2} + C_0 \int_{U_i} |N|^{2+\gamma_2},
\]

(4.4)

\[
\int_{U_i} |DN|^2 \leq C_0 m_0 \ell_i^{m+2-2\beta_2},
\]

(4.5)

\[
\|N\|_{C^{0}\left(U_i\right)} + \sup_{p \in \text{sp}T \cap p^{-1}(U_i)} |p - p(p)| \leq C_0 m_0^{1/2m} \ell_i^{1+\beta_2},
\]

(4.6)

\[
\text{Lip}(N|_{U_i}) \leq C_0 m_0^{\gamma_2} \ell_i^{\gamma_2},
\]

(4.7)

\[
M(T \cap p^{-1}(V_i)) + M(T \cap p^{-1}(V_i)) \leq C_0 m_0^{1+\gamma_2} \ell_i^{m+2+\gamma_2}.
\]

(4.8)

To prove these estimates, observe first that \( \sum_{H \in \mathcal{W}(L_i)} \ell(H)^m \leq C_0 \ell_i^m \), because all \( H \in \mathcal{W}(L_i) \) are disjoint and contained in a ball of radius comparable to \( \ell_i \). This in turn implies that \( \sum_{H \in \mathcal{W}(L_i)} \ell(H)^{m+\varepsilon} \leq C_0 \ell_i^{m+\varepsilon} \), because \( \ell(H) \leq \ell_i \) for any \( H \in \mathcal{W}(L) \). Thus:

- (4.4) follows summing the estimate of \([4, \text{Theorem 2.4 (2.4)}]\) applied with \( a = 1 \) to \( \Phi(H) \) with \( H \in \mathcal{W}(L_i) \);
- (4.5) follows from summing the estimate of \([4, \text{Theorem 2.4 (2.3)}]\) applied to \( \Phi(H) \) with \( H \in \mathcal{W}(L_i) \);
- (4.6) follows from \([4, \text{Theorem 2.4 (2.1)}]\) and \([4, \text{Corollary 2.2 (ii)}]\);
- (4.7) follows from \([4, \text{Theorem 2.4 (2.1)}]\);
- (4.8) follows summing \([4, \text{Theorem 2.4 (2.2)}]\) applied to \( \Phi(H) \) with \( H \in \mathcal{W}(L_i) \).

The last ingredient for the completion of the proof of Proposition 3.5 are the following three key estimates which are derived from the analysis of the construction of the center manifold in \([4]\).

**Lemma 4.5.** Under the assumptions of Proposition 3.5, it holds

\[
\sum_i \left( \inf_{B_i} \varphi_r \right) m_0 \ell_i^{m+2+\gamma_2/4} \leq C_0 D(r),
\]

(4.9)

\[
\sum_i m_0 \ell_i^{m+2+\gamma_2/4} \leq C_0 (D(r) + rD'(r)),
\]

(4.10)

for some geometric constant \( C_0 \). Moreover, for every \( t > 0 \) there exists \( C(t) > 0 \) and \( \gamma(t) > 0 \) such that

\[
\sup_t m_0^{\left[ \ell_i^t + \left( \inf_{B_i} \varphi_r \right)^{t/2} \right]} \leq C(t)D(r)^{\gamma(t)}.
\]

(4.11)

**Proof.** Recall that, from \([4, \text{Propositions 3.1 and 3.4}]\), we have, for some geometric positive constant \( c_0 \)

\[
\int_{B_i} |N|^2 \geq c_0 m_0^{1/m} \ell_i^{m+2+2\beta_2} \quad \text{if} \quad L_i \in \mathcal{W}_h,
\]

(4.12)

\[
\int_{B_i} |DN|^2 \geq c_0 m_0 \ell_i^{m+2-2\beta_2} \quad \text{if} \quad L_i \in \mathcal{W}_e.
\]

(4.13)
Therefore, by Lemma 3.6, (4.2), (4.12) and (4.13), it follows easily that, for suitably chosen \( \gamma(t), C(t) > 0 \),

\[
\sup_i m_0^t \left[ \ell_i^t + \left( \inf_{B^t} \varphi_r \right)^{t/2} \right] \leq C(t) \sup_i \left( \int_{B^t} \varphi_r(|DN|^2 + |N|^2) \right)^{\gamma(t)} \leq C(t) D(r)^{\gamma(t)}.
\]

Next, (4.9) follows similarly because the \( B^t \) are disjoint and \( 8 \beta_2 < \gamma_2 \):

\[
\sum_i \left( \inf_{B^t} \varphi_r \right) m_0^t \ell_i^{m+2+\gamma_2/4} \leq C \sum_i \int_{B^t} \varphi_r(|DN|^2 + |N|^2)^{\gamma(t)} \leq CD(r).
\]

Finally, arguing as above we conclude that

\[
\sum_i m_0^t \ell_i^{m+2+\gamma_2/4} \leq C \int_{B_r(q)}(|DN|^2 + |N|^2)^{\gamma(t)} \leq C(D(r) + rD'(r)).
\]

4.3. Proof of Proposition 3.5: (3.6) and (3.7). We can now pass to estimate the errors terms in (3.6) and (3.7) in order to conclude the proof of Proposition 3.5. Unless otherwise specified, the constants denoted by \( C \) will be assumed to be geometric (i.e. to depend only upon the parameters introduced in [4]).

Errors of type 1. By [4, Theorem 1.12], the map \( \varphi \) defining the center manifold satisfies

\[
\|D\varphi\|_{C^2, r} \leq C m_0^{1/2},
\]

which in turn implies \( \|H_M\|_{L^\infty} + \|DH_M\|_{L^\infty} \leq C m_0^{1/2} \) (recall that \( H_M \) denotes the mean curvature of \( M \)). Therefore, by (4.3), (4.4), (4.9) and (4.11), we get

\[
|\text{Err}_1^0| \leq C_0 \int_M \varphi_r |H_M| |\eta \circ N|
\leq C_0 m_0^{1/2} \sum_j \left( \left( \sup_{U^r} \varphi_r \right) m_0 \ell_j^{2+m+\gamma_2} + C_0 \int_{U^r} \varphi_r |N|^{2+\gamma_2} \right)
\leq CD(r)^{1+\gamma_3} + C \sum_j m_0^{1/2} \ell_j^{2(1+\beta_2)} \int_{U^r} \varphi_r |N|^2 \leq C(\gamma_3) D(r)^{1+\gamma_3},
\]

provided \( \gamma_3 > 0 \) is sufficiently small depending only upon \( m, \beta_2, \delta_2 \) and \( \gamma_2 \). Analogously

\[
|\text{Err}_1^1| \leq C r^{-1} \int_M (|H_M| + |DYH_M|) |\eta \circ N|
\leq C r^{-1} m_0^{1/2} \sum_j \left( m_0 \ell_j^{2+m+\gamma_2} + C \int_{U^r} |N|^{2+\gamma_2} \right) \leq C(\gamma_3) r^{-1} D(r)^{\gamma_3}(D(r) + rD'(r)).
\]

Errors of type 2. From \( \|A\|_{C^0} \leq C\|D\varphi\|_{C^2} \leq C m_0^{1/2} \leq C \varepsilon_3 \), it follows that \( \text{Err}_2^0 \leq C \varepsilon_3^2 \Sigma(r) \). Moreover, since \( |DX_i| \leq Cr^{-1} \), Lemma 3.6 gives

\[
|\text{Err}_2^1| \leq C r^{-1} \int_{B_r(p_0)} |N|^2 + C \int \varphi_r |N||DN| \leq CD(r).
\]
Errors of type 3. Clearly, we have
\[ |\text{Err}_3^0| \leq \varphi_r \left( |DN|^2 |N| + |DN|^4 \right) + C r^{-1} \int_{B_r(q)} |DN|^3 |N| + C r^{-1} \int_{B_r(q)} |DN| |N|^2. \]

We estimate separately the three terms (recall that \( \gamma_2 > 4\delta_2 \)):
\[
I_1 \leq \int_{B_r(p_0)} \varphi_r(|N|^2 |DN| + |DN|^3) \leq I_3 + C \sum_j \sup_{U_j} \varphi_r m_0^{1+\gamma_2} \ell_j^{m+2+\gamma_2/2} \tag{4.9} \leq \tag{4.11}
I_3 + C(\gamma_3) D(r)^{1+\gamma_3},
\]
\[
I_2 \leq C r^{-1} \sum_j m_0^{1+1/2m+\gamma_2} \ell_j^{m+3+\beta_2+\gamma_2/2} \leq C \sum_j m_0^{1+1/2m+\gamma_2} \ell_j^{m+2+\beta_2+\gamma_2/2} \inf_{B_j} \varphi_r \tag{4.9} \& (4.11) \leq C(\gamma_3) D(r)^{1+\gamma_3},
\]
\[
I_3 \leq C r^{-1} \sum_j m_0^{2\gamma_2} \epsilon_j^{2} \int_{U_j} |N|^2 \leq C \gamma_3 r^{-1} D(r)^{\gamma_3} \int_{B_r(q)} |N|^2 \leq C(\gamma_3) D(r)^{1+\gamma_3}, \tag{3.18}
\]

provided \( \gamma_3 > 0 \) is sufficiently small. For what concerns the inner variations, we have
\[ |\text{Err}_3^i| \leq C \int_{B_\gamma(q)} \left( r^{-1} |DN|^3 + r^{-1} |DN|^2 |N| + r^{-1} |DN||N|^2 \right). \]

The last integrand corresponds to \( I_3 \), while the remaining part can be estimated as follows:
\[
\int_{B_\gamma(q)} r^{-1} (|DN|^3 + |DN|^2 |N|) \leq C \sum_j r^{-1} (m_0^{2\gamma_2} \epsilon_j^{2} + m_0^{1/2m} \ell_j^{1+\beta_2}) \int_{U_j} |DN|^2 \leq C(\gamma_3) r^{-1} D(r)^{\gamma_3} \int_{B_r(q)} |DN|^2 \leq C(\gamma_3) D(r)^{\gamma_3} (D'(r) + r^{-1} D(r)). \tag{4.11}
\]

Errors of type 4. We compute explicitly
\[ |DX_o(p)| \leq 2 |p - p_r(p)| \frac{|Dd(p_r(p), q)|}{r} + \varphi_r(p) |D(p - p_r(p))| \leq C \left( \frac{|p - p_r(p)|}{r} + \varphi_r(p) \right). \]

It follows readily from (3.19), (4.6) and (4.8) that
\[
|\text{Err}_4^0| \leq \sum_i C \left( r^{-1} m_0^{1/2m} \ell_i^{1+\beta_2} + \sup_{U_i} \varphi_r \right) m_0^{1+\gamma_2} \ell_i^{m+2+\gamma_2} \tag{4.2} \& (4.3) \leq C \sum_i \left[ m_0^{\gamma_2} \ell_i^{\gamma_2/4} \right] \inf_{B_i} \varphi_r m_0 \ell_i^{m+2+\gamma_2/4} \tag{4.9} \& (4.11) \leq C(\gamma_3) D(r)^{1+\gamma_3}. \tag{4.14}
\]
Similarly, since $|DX_i| \leq C r^{-1}$, we get
\[
\text{Err}_4^i \leq C r^{-1} \sum_j \left( m_0^{\gamma_2} \ell_j^{\gamma_2/2} \right) m_0 \ell_j^{m+2+\gamma_2/2} \leq C(\gamma_3)D(r)^{\gamma_3} (D'(r) + r^{-1}D(r))
\]

**Errors of type 5.** Integrating by part Err_5, we get
\[
\text{Err}_5 = \left| \int \langle X^+, h(\mathbf{T}(p)) \rangle d\|T\| \right| \leq \left( \int \langle X^+, h(\mathbf{T}_F(p)) \rangle d\|T\| \right)_{I_2}
\]
\[
+ \int_{spt(T)\setminus\text{Im}(F)} |X^+| |h(\mathbf{T}(p))| d\|T\| + \int_{\text{Im}(F)\setminus spt(T)} |X^+| |h(\mathbf{T}_F(p))| d\|T\|,
\]
where $h(\mathbf{\bar{\lambda}})$ is the trace of $A_\Sigma$ on the $m$-vector $\mathbf{\bar{\lambda}}$, i.e. $h(\mathbf{\bar{\lambda}}) := \sum_{k=1}^m A_\Sigma (v_k, v_k)$. Since $|X| \leq C$, $I_1$ can be easily estimated as $\text{Err}_4$.

For what concerns $I_2$, we argue differently for the outer and the inner variations. For $\text{Err}_5^i$, observe that $|X^+((p))| = \varphi_r(p) \|p_{T^\bot_\Sigma (p)} (p - p(p))\|$. On the other hand, we also have
\[
|p_{T^\bot_\Sigma (p)} (p - p(p))| \leq C \epsilon(\Sigma) \|p - p(p)\|^2 \leq C m_0^{1/2} \|p - p(p)\|^2 \quad \forall p \in \Sigma.
\]

Therefore, we can estimate
\[
I_2^o \leq C m_0 \int \varphi_r |N|^2 \leq C \epsilon_3^2 \Sigma(r).
\]

For the inner variations, denote by $v_1, \ldots, v_t$ an orthonormal frame for $T_p \Sigma^\bot$ of class $C^{2,\epsilon_0}$ (cf. [5, Appendix A]) and set $h^i_p(\mathbf{\bar{\lambda}}) := -\sum_{k=1}^m D_k^p \nu_j(p, v_k)$ whenever $v_1 \land \ldots \land v_m = \mathbf{\bar{\lambda}}$ is an $m$-vector of $T_p \Sigma$ (with $v_1, \ldots, v_m$ orthonormal). For the sake of simplicity, write
\[
h_p := h_p(\mathbf{T}_F(p)) \quad \text{and} \quad h_p = \sum_{j=1}^t h_p^j \nu_j(p),
\]
\[
h_p^j(p) := h_p^j(\mathbf{T}_F(p)) \quad \text{and} \quad h_p(p) = \sum_{j=1}^t h_p^j(p) \nu_j(p).
\]

Consider the exponential map $\mathbf{exp}_{p(p)} : T_{p(p)} \Sigma \rightarrow \Sigma$ and its inverse $\mathbf{exp}_{p(p)}^{-1}$. Recall that:

- the geodesic distance $d_\Sigma(p, q)$ is comparable to $|p - q|$ up to a constant factor;
- $\nu_j$ is $C^{2,\epsilon_0}$ and $\|D\nu_j\|_{C^{1,\epsilon_0}} \leq C m_0^{1/2}$;
- $\mathbf{exp}_{p(p)}$ and $\mathbf{exp}_{p(p)}^{-1}$ are both $C^{2,\epsilon_0}$ and $\|d\mathbf{exp}_{p(p)}\|_{C^{1,\epsilon_0}} + \|d\mathbf{exp}_{p(p)}^{-1}\|_{C^{1,\epsilon_0}} \leq m_0^{1/2}$;
- $|h_p| \leq C \|A_\Sigma\|_{C^0} \leq C m_0^{1/2}$.
where all the constants involved are just geometric. We then conclude that
\[
    h_p - h_{p(p)} = \sum_j \nu_j(p)(h_p^j - h_{p(p)}^j) + \sum_j (\nu_j(p) - \nu_j(p(p))) h_{p(p)}^j
\]
\[
= \sum_j \nu_j(p)(h_p^j - h_{p(p)}^j) + \sum_j \nu_j(p) \cdot \text{ex}_{p(p)}^{-1}(p) h_{p(p)}^j + O(|p - p(p)|^2).
\]
(4.15)

On the other hand, \(X_i(p) = Y(p(p))\) is tangent to \(M\) in \(p(p)\) and hence orthogonal to \(h_{p(p)}\). Thus
\[
    \langle X_i(p), h_p \rangle = \langle X^i(p), (h_p - h_{p(p)}) \rangle = \sum_j \langle X_i(p), \nu_j(p) \rangle \cdot \text{ex}_{p(p)}^{-1}(p) h_{p(p)}^j
\]
\[
    + \sum_j (\nu_j(p), X_i(p)) (h_p^j - h_{p(p)}^j) + O(|p - p(p)|^2)
\]
\[
= \sum_j \langle X_i(p), \nu_j(p) \rangle \cdot \text{ex}_{p(p)}^{-1}(p) h_{p(p)}^j
\]
\[
+ O\left(|\nabla (p(p))| |p - p(p)| + |p - p(p)|^2\right),
\]
(4.16)
where we used elementary calculus to infer that \(|\langle X_i(p), \nu_j(p) \rangle| \leq C|p - p(p)|\) and
\[
|h_p^j - h_{p(p)}^j| \leq C \left(|\nabla (p(p))| + |p - p(p)|\right).
\]

We only need that the constants \(C\) appearing in the above inequalities are bounded by a geometric factor: in fact they enjoy explicit bounds in terms of \(m^{ij}_0\) which are at least linear, but such degree of precision is not needed. Finally recalling that \(p \in \text{spt}(T_F)\), we can bound \(|p - p(p)| \leq |N(p)|\) and \(|\nabla (p(p))| \leq C|DN(p(p))|\). We therefore conclude the estimate
\[
    \langle X_i(p), h_p \rangle = \sum_j \langle X_i(p), \nu_j(p) \rangle \cdot \text{ex}_{p(p)}^{-1}(p) h_{p(p)}^j + O(|N|^2(p(p)) + |DN|^2(p(p))).
\]

We combine it with the expansion of the area functional in [5, Theorem 3.2] to conclude the estimate on \(I_2^i\). Recalling that \(p(F_i(x)) = x\) we get
\[
I_2^i = \left\| \sum_{i=1}^Q \langle Y, h_{F_i} \rangle \right\| \leq \sum_{i=1}^Q \left\| \sum_{j=1}^i \langle Y, h_{F_1} \rangle JF_i \right\| = \sum_{i=1}^Q \int_M \sum_{j=1}^i \langle Y, h_{F_1} \rangle JF_i \right\| + C \int_M \varphi(|N| + |DN|)
\]
\[
\leq \left| \sum_{j=1}^Q \sum_{i=1}^j \int_M \varphi(|N| + |DN|) \right. + C \int_M \varphi(|N| + |DN|)
\]
\[
= \left| \sum_{j=1}^Q \int_M \varphi(|N| + |DN|) \right. + C \int_M \varphi(|N| + |DN|)
\]
\[
\leq C \varphi(|N| + |DN|) + C|N| + C|N|.
\]
Next consider that $|\langle Y, Du_{j} \cdot v \rangle| \leq C \varphi_{r} \|A_{\Sigma}\|_{C^{0}} |v| \leq C \varphi_{r} m_{0}^{1/2} |v|$ for every tangent vector $v$ and $|h^{j}_{\Sigma}| \leq C \|A_{\Sigma}\|_{C^{0}} \leq m_{0}^{1/2}$. We thus conclude with the estimate

$$I^{j}_{2} \leq C m_{0} \int_{M} \varphi_{r} |\eta \circ N| + C \int_{M} \varphi_{r} (|N|^{2} + |DN|^{2}) =: J_{1} + J_{2}.$$ 

Clearly $J_{1}$ can be estimated as $Err_{1}^{j}$ and $J_{2}$ as $Err_{2}^{j}$, thus concluding the proof.

5. BOUNDEDNESS OF THE FREQUENCY

In this section we prove that the frequency function $I_{j}$ remains bounded along the different center manifolds corresponding to the intervals of flattening. To simplify the notation, we set $p_{j} := \Phi_{j}(0)$ and write simply $B_{\rho}$ in place of $B_{\rho}(p_{j})$.

Theorem 5.1 (Boundedness of the frequency functions). Let $T$ be as in Assumption 2.1. If the intervals of flattening are $j_{0} < \infty$, then there is $\rho > 0$ such that

$$H_{j_{0}} > 0 \text{ on } ]0, \rho[ \text{ and } \limsup_{r \to 0} I_{j_{0}}(r) < \infty. \quad (5.1)$$

If the intervals of flattening are infinitely many, then there is a number $j_{0} \in \mathbb{N}$ such that

$$H_{j} > 0 \text{ on } ]s_{j}^{2}/t_{j}, 3[ \text{ for all } j \geq j_{0} \text{ and } \sup_{j \geq j_{0}} \sup_{r \in ]s_{j}^{2}/t_{j}, 3[} I_{j}(r) < \infty. \quad (5.2)$$

Proof. Consider the first alternative. We claim that for every $r > 0$ there is a radius $0 < \rho < r$ such that $H(\rho) = H_{j_{0}}(\rho) > 0$. Otherwise $N_{j_{0}}$ vanishes identically on some $B_{r}$. By [4, Propositions 3.1 and 3.4] and the condition (Stop), this is possible only if no cube of the Whitney decomposition $\mathcal{W}^{(j_{0})}$ intersects the projection of $B_{r}$ onto the plane $\pi$ (the reference plane for the construction of the center manifold). But then $T_{j_{0}}$ would coincide with $Q \llbracket M \rrbracket$ in $B_{3r/4}$ and 0 would be a regular point of $T_{j_{0}}$ and, therefore, of $T$.

Next we claim that $H(r) > 0$ for every $r \leq \rho$. If not, let $r_{0}$ be the largest zero of $H$ which is smaller than $\rho$. By Theorem 3.2, there is a constant $C$ such that $I(r) \leq C(1 + I(\rho))$ for every $r \in ]r_{0}, \rho[$. By letting $r \downarrow r_{0}$, we then conclude

$$r_{0}D(r_{0}) \leq C(1 + I(\rho))H(r_{0}) = 0,$$

that is, $N_{j}|_{B_{r_{0}}} \equiv 0$ which we have already excluded. Therefore, since $H > 0$ on $]0, \rho[$, we can now apply Theorem 3.2 to conclude (5.1).

In the second case, we partition the extrema $t_{j}$ of the intervals of flattening into two different classes: the class $(A)$ when $t_{j} = s_{j-1}$ and the class $(B)$ when $t_{j} < s_{j-1}$. If $t_{j}$ belongs to $(A)$, set $r := s_{j-1}^{2}/t_{j-1}$. Let $L \in \mathcal{W}^{(j-1)}$ be a cube of the Whitney decomposition such that $c_{\Sigma} r \leq \ell(L)$ and $L \cap B_{r}(0, \pi) \neq \emptyset$. We are in the position to apply [4, Proposition 3.7] for the comparison of two center manifolds: there exists a constant $c_{t} > 0$ such that

$$\int_{B_{r} \cap M_{j}} |N_{j}|^{2} \geq c_{t} m_{0}^{j} := c_{t} \max \{E(T_{j}, B_{0, \sqrt{m}}), c(\Sigma_{j})^{2} \},$$

which obviously gives $H_{N_{j}}(3) \geq c m_{0}^{j}$. By (3.4), we conclude that $I_{N_{j}}(3)$ is smaller than a given constant, independent of $j$. Arguing as above, we also conclude that, for $j$ large...
Let \( J \in \mathcal{A} \). Assuming \( j \in (0,1] \) such that \( E((t_0,t_j)_t) \geq \epsilon_3^2 > \epsilon_3^3 \). Thus, by Lemma 5.2 below, we conclude lim inf \( t_j \rightarrow \infty \) \( H_{N_j}(3) = 0 \). Since \( D_{N_j}(3) \leq C \), we achieve that \( \lim_{t_j \rightarrow \infty} I_{N_j}(3) < +\infty \), and conclude as before.

**Lemma 5.2.** Assume the intervals of flattening are infinitely many and \( r_j \in (\sqrt{3}, 3] \) is a subsequence (not relabeled) with \( \lim_j \| N_j \|_{L^2(B_r \setminus B_{r_j/2})} = 0 \). If \( \epsilon_3 \) is sufficiently small, then \( E(T_j, B_{r_j}) \rightarrow 0 \).

**Proof.** Note that, if \( r_j \rightarrow 0 \), then necessarily \( E(T_j, B_{r_j}) \rightarrow 0 \) by Proposition 2.2(iv). Therefore, up to a subsequence, we can assume the existence of \( c > 0 \) such that

\[
\int_{B_r \setminus B_{r_j}} \mid N_j \mid^2 \rightarrow 0, \tag{5.4}
\]

and the existence of an area-minimizing cone \( S \) such that \((t_{0,j})_t) T \rightarrow S\). Note that, by (5.3), \( S \) is not a multiplicity \( Q \) flat \( m \)-plane. Consider the orthogonal projection \( q_j : \mathbb{R}^{m+n} \rightarrow \pi_{t_j} \), where \( \pi_{t_j} \) is the \( m \)-dimensional plane of the construction of the center manifold \( M_j \). Assuming \( \epsilon_3 \) is sufficiently small, we have \( U_j := B_{1/3}^{1/3} \setminus B_{1/3}^{1/3} \subset q_j(B_r \setminus B_{r_j/2}) \). Consider the Whitney decomposition \( \mathcal{W}(j) \) leading to the construction of \( M_j \); if the decomposition is empty, then \( T_j \) coincides with \( M_j \). Otherwise, set

\[
d_j := \max \{ \ell(J) : J \in \mathcal{W}(j) \text{ and } J \cap U_j \neq \emptyset \}.
\]

Let \( J_j \in \mathcal{W}(j) \) be such that \( U_j \cap J_j \neq \emptyset \) and \( d_j = \ell(J_j) \). If the stopping condition for \( J_j \) is either (HT) or (EX), recalling that \( \ell(J_j) \leq c_r r \), we choose a ball \( B^j \subset U_j \) of radius \( d_j^{1/2} \) and at distance at most \( \sqrt{m} d_j \) from \( J_j \). If the stopping condition for \( J_j \) is (NN), \( J_j \) is in the domain of influence of \( K_j \in \mathcal{W}(j) \). By Proposition 2.2 we can then choose a ball \( B^j \subset U_j \) of radius \( \ell(K_j) / 8 \) at distance at most \( 3 \sqrt{m} \ell(K_j) \) from \( K_j \). If the stopping condition is (HT), we then have by \( [4, \text{Proposition 3.1}] \)

\[
\int_{B_r \setminus B_{r_j}} \mid N_j \mid^2 \geq \int_{\Phi_{j}(B^j)} \mid N_j \mid^2 \geq c(m_0)^{1/2} \alpha d_j^{m+2+2\beta_2}.
\]
If the stopping condition is either (NN) or (EX), by [4, Proposition 3.3] we have
\[ \int_{B_r \setminus B_{2r}} |N_j|^2 \geq \int_{\Phi_j(B_i)} |N_j|^2 \geq cd_j^2 \int_{\Phi_j(B_i)} |DN_j|^2 \geq c m_d j^{m+4-2d_j}. \quad (5.5) \]
In both cases we conclude that \( d_j \to 0 \).

By [4, Corollary 2.2], \( spt(T_j) \cap \Phi_j(U_j) \) is contained in a \( d_j \)-tubular neighborhood of \( M_j \), which we denote by \( U_j \). Moreover, again assuming that \( \varepsilon_j \) is sufficiently small, we can assume \( B_t \setminus B_s \cap M_j \subset \Phi_j(U_j) \) for some appropriate choice of \( s < t \), independent of \( j \). Finally, by [4, Theorem 1.17] we can assume that (up to subsequences) \( M_j \) converges to \( M \) in \( C^3 \). We thus conclude that \( S \setminus B_t \setminus B_s = Q_0 [M \cap \partial B_t \setminus B_s] \) for some integer \( Q_0 \). Observe also that, if \( p_j : U_j \to M_j \) is the least distance projection onto \( M_j \), by [4, Theorem 2.4] we also have \( (p_j)_t(\Phi_j(B_t) \setminus B_{2r}) = Q [M_j \cap \partial B_t \setminus B_s] \). We therefore conclude that \( Q_0 = Q \). Since \( S \) is a cone without boundary, \( \partial (S \setminus B_t) = Q [M \cap \partial B_t] \), i.e. \( S \setminus B_t = Q [0] \times [M \cap \partial B_t] \).

By Allard’s regularity theorem, \( S \) is regular in a neighborhood of 0 and, therefore, it is an \( m \)-plane with multiplicity \( Q \), which gives the desired contradiction. \( \square \)

A corollary of Theorem 5.1 is the following.

**Corollary 5.3** (Reverse Sobolev). Let \( T \) be as in Assumption 2.1. Then, there exists a constant \( C > 0 \) which depends on \( T \) but not on \( j \) such that, for every \( j \) and for every \( r \in ]\frac{4}{7}, 1] \), there is \( s \in ]\frac{3}{2}r, 3r[ \) such that
\[ \int_{B_s(\Phi_j(0))} |DN_j|^2 \leq C \int_{B_r(\Phi_j(0))} |N_j|^2. \quad (5.6) \]

**Proof.** We start observing that, by the Coarea Formula,
\[ H_j(3r) = \int_{B_{3r}(\Phi_j(0)) \setminus B_{3r/2}(\Phi_j(0))} \frac{2|N_j|^2}{d(p)} = 2 \int_{3r/2}^3 1 \int_{\partial B_t(\Phi_j(0))} |N_j|^2 dt, \]
whereas, using Fubini,
\[ \int_{\frac{3}{2}r}^{3r} \int_{B_t(\Phi_j(0))} |DN_j|^2 dt = \int_{M_j} |DN_j|^2(x) \int_{|x|, \infty} 1(x) dt \mathcal{H}^m(x) = \frac{3}{2} r D_j(3r). \]

So, by Theorem 5.1, there exists \( C > 0 \) depending on the current \( T \) such that
\[ \int_{\frac{3}{2}r}^{3r} dt \int_{B_t(\Phi_j(0))} |DN_j|^2 = \frac{3}{2} r D_j(3r) \leq C H_j(3r) = C \int_{\frac{3}{2}r}^{3r} dt \int_{\partial B_t(\Phi_j(0))} |N_j|^2. \]

Therefore, there must be \( s \in ]\frac{3}{2}r, 3r[ \) such that
\[ \int_{B_s(\Phi_j(0))} |DN_j|^2 \leq \frac{C}{s} \int_{\partial B_s(\Phi_j(0))} |N_j|^2. \quad (5.7) \]
Fix now any \( \sigma \in ]s/2, s[ \) and any point \( x \in \partial B_s(\Phi_j(0)) \). Consider the geodesic line \( \gamma \) passing through \( x \) and \( \Phi_j(0) \) and let \( \hat{\gamma} \) be the arc on \( \gamma \) having one endpoint \( \bar{x} \) in \( \partial B_\sigma(\Phi_j(0)) \) and
one endpoint equal to \( x \). Using [3, Proposition 2.1(b)] and the fundamental theorem of calculus, we easily conclude
\[
|N_j(x)| \leq |N_j(\bar{x})| + \int_{\bar{x}} |DN_j||N_j|.
\]
Integrating this inequality in \( x \) and recalling that \( \sigma > s/2 \) we then easily conclude
\[
\int_{\partial B_s(\Phi_j(0))} |N_j|^2 \leq C \int_{B_s(\Phi_j(0))} |N_j|^2 + C \int_{B_s(\Phi_j(0))} |N_j||DN_j|.
\]
We further integrate in \( \sigma \) between \( s/2 \) and \( s \) to achieve
\[
s \int_{\partial B_s(\Phi_j(0))} |N_j|^2 \leq C \int_{B_s(\Phi_j(0))} (|N_j|^2 + s |N_j||DN_j|) \leq \frac{s^2}{2} \int_{B_s(\Phi_j(0))} |DN_j|^2 + C \int_{B_s(\Phi_j(0))} |N_j|^2.
\]
Combining (5.8) with (5.7) we easily conclude (5.6).

6. Final blow-up sequence and capacitary argument

6.1. Blow-up maps. Let \( T \) be a current as in the Assumption 2.1. By Proposition 2.2 we can assume that for each radius \( r_k \) there is an interval of flattening \( I_{j(k)} = [s_{j(k)}, t_{j(k)}] \) containing \( r_k \). We define next the sequence of “blow-up maps” which will lead to the proof of Almgren’s partial regularity result Theorem 0.3. To this aim, for \( k \) large enough, we define \( \bar{s}_k \) so that the radius \( \frac{\bar{s}_k}{t_{j(k)}} \in \left[ \frac{3}{2} \frac{r_k}{t_{j(k)}}, 3 \frac{r_k}{t_{j(k)}} \right] \) is the radius provided in Corollary 5.3 applied to \( r = \frac{r_k}{t_{j(k)}} \). We then set \( \bar{r}_k := \frac{2 \bar{s}_k}{3 t_{j(k)}} \) and rescale and translate currents and maps accordingly:

\begin{align*}
(\text{BU1}) \quad & \tilde{T}_k = (t_{0,r_k})_2 T_{j(k)} = ((t_{0,\bar{r}_k t_{j(k)}})_2 T) \ll B_{6/\sqrt{m}/r_k}, \quad \bar{\Sigma}_k = t_{0,\bar{r}_k} (\Sigma_{j(k)}) \\
& \text{and } \tilde{\mathcal{M}}_k := t_{0,\bar{r}_k} (\mathcal{M}_{j(k)}); \\
(\text{BU2}) \quad & \bar{N}_k : \bar{\mathcal{M}}_k \to \mathbb{R}^{m+n} \text{ are the rescaled } \bar{\mathcal{M}}_k\text{-normal approximations given by} \\
& \quad \bar{N}_k(p) = \frac{1}{\bar{r}_k} N_{j(k)}(\bar{r}_k p). \quad (6.1)
\end{align*}

Since by assumption \( T_0 \Sigma = \mathbb{R}^{m+n} \times \{0\} \), the ambient manifolds \( \bar{\Sigma}_k \) converge to \( \mathbb{R}^{m+n} \times \{0\} \) locally in \( C^{3,\bar{\varepsilon}_0} \) (more precisely to a "large portion" of \( \mathbb{R}^{m+n} \times \{0\} \), because \( B_{6/\sqrt{m}} \subset B_{6/\sqrt{m}/r_k} \)). Moreover, since \( \frac{1}{2} < \frac{r_k}{\bar{r}_k t_{j(k)}} < 1 \), it follows from Proposition 1.3 that
\[
E(\bar{T}_k, B_{\frac{1}{2}}) \leq C E(T, B_{r_k}) \to 0.
\]

By the standard regularity theory of area minimizing currents and Assumption 2.1, this implies that \( \bar{T}_k \) locally converge (and supports converge locally in the Hausdorff sense) to (a large portion of) a minimizing tangent cone which is an \( m \)-plane with multiplicity
Finally, (iii) is a simple consequence of Corollary 5.3.

In the next lemma, we show that the rescaled center manifolds $\mathcal{M}_k$ converge locally to the flat $m$-plane $\pi_0$, thus leading to the following natural definition for the blow-up maps $N^k_B : B_3 \subset \mathbb{R}^m \to A_Q(\mathbb{R}^{m+n})$:

$$N^k_B(x) := h^{-1}_k \mathcal{N}_k(e_k(x)),$$

where $h_k := \|\mathcal{N}_k\|_{L^2(B_{\frac{3}{2}})}$ and $e_k : B_3 \subset \mathbb{R}^m \cong T_{\bar{p}_k} \mathcal{M}_k \to \mathcal{M}_k$ denotes the exponential map at $\bar{p}_k = \Phi_{j(k)}(0)/r_k$.

**Lemma 6.1** (Vanishing lemma). Under the Assumption 2.1, the following hold:

(i) we can assume, without loss of generality, $\bar{r}_k m^j_0(k) \to 0$;

(ii) the rescaled center manifolds $\mathcal{M}_k$ converge (up to subsequences) to $\mathbb{R}^m \times \{0\}$ in $C^{3,\kappa/2}(B_4)$ and the maps $e_k$ converge in $C^{2,\kappa/2}$ to the identity map $id : B_3 \to B_3$;

(iii) there exists a constant $C > 0$, depending only $T$, such that, for every $k$,

$$\int_{B_{\frac{3}{2}}} |DN^k_B|^2 \leq C.\quad (6.4)$$

**Proof.** To show (i), note that, if $\liminf_k \bar{r}_k > 0$, we can extract a further subsequence and assume that $\lim_k \bar{r}_k > 0$. Observe that then $\bar{r} := \limsup_k \frac{t_{j(k)}}{\bar{r}_k} < \infty$. Since $r_k \downarrow 0$, we necessarily conclude that $t_{j(k)} \downarrow 0$ and hence $c(\Sigma_{j(k)}) \to 0$. Moreover $E(T, B_6, m_{j(k)}) \leq C(\bar{r})E(\bar{T}_k, B_6, m_{j(k)-1}) \to 0$ because $\bar{T}_k$ converges to $Q[\pi_0]$. We conclude $\bar{r}_k m^j_0(k) \to 0$. On the other hand if $\lim_k \bar{r}_k = 0$ then (i) follows trivially from the fact that $m^j_0$ is a bounded sequence.

Next, using $\bar{r}_k m^j_0(k) \to 0$ and the estimate of [4, Theorem 1.17], it follows easily that $\mathcal{M}_k - \bar{p}_k$ converge (up to subsequences) to a plane in $C^{3,\kappa/2}(B_4)$. By Proposition 2.2 (v) we deduce easily that such plane is in fact $\pi_0$. Since 0 belongs to the support of $T_{j(k)}$ we conclude for the same reason that $\mathcal{M}_k$ is converging to $\pi_0$ as well. Therefore, by Proposition A.4 the maps $e_k$ converge to the identity in $C^{2,\kappa/2}$ (indeed, by standard arguments they must converge to the exponential map on the – totally geodesic! – submanifold $\mathbb{R}^m \times \{0\}$).

Finally, (iii) is a simple consequence of Corollary 5.3.

The main result about the blow-up maps $N^b_k$ is the following.

**Theorem 6.2** (Final blow-up). Up to subsequences, the maps $N^b_k$ converge strongly in $L^2(B_{\frac{3}{2}})$ to a function $N^b_\infty : B_{\frac{3}{2}} \to A_Q(\{0\} \times \mathbb{R}^n \times \{0\})$ which is Dir-minimizing in $B_t$ for every $t \in \left[\frac{5}{3}, \frac{3}{2}\right]$ and satisfies $\|N^b_\infty\|_{L^2(B_{\frac{3}{2}})} = 1$ and $\eta \circ N^b_\infty \equiv 0$.

We postpone the proof of Theorem 6.2 to the next section and show next Theorem 0.3.
6.2. Proof of Theorem 0.3: capacitary argument. Let \( N_b^b \) be as in Theorem 6.2 and \( \Upsilon := \{ x \in \bar{B}_1 : N_b^b(x) = Q \} \).

Since \( \eta \circ N_b^b \equiv 0 \) and \( \| N_b^b \|_{L^2(B_{3/2})} = 1 \), from the regularity of Dir-minimizing \( Q \)-valued functions (cf. [3, Theorem 0.11]), we know that \( \mathcal{H}^{m-2+\alpha}_\infty(\Upsilon) = 0 \). We show in the next three steps that this contradicts Assumption 0.4.

**Step 1.** We cover \( \Upsilon \) by balls \( \{ B_{\sigma_i}(x_i) \} \) in such a way that \( \sum_i \omega_{m-2+\alpha}(4\sigma_i)^{m-2+\alpha} \leq \frac{\eta}{2} \), where \( \eta \) is the constant in (6.2). By the compactness of \( \Upsilon \), such a covering can be chosen finite. We can therefore choose a \( \bar{\sigma} > 0 \) so that the \( 5\bar{\sigma} \)-neighborhood of \( \Upsilon \) is covered by \( \{ B_{\sigma_i}(x_i) \} \). Denote by \( \Lambda_k \) the set of multiplicity \( Q \) points of \( \bar{T}_k \) far away from the singular set \( \Upsilon \):

\[
\Lambda_k := \{ p \in D_Q(\bar{T}_k) \cap B_1 : \text{dist}(p, \Upsilon) > 4\bar{\sigma} \}.
\]

Clearly, \( \mathcal{H}^{m-2+\alpha}_\infty(\Lambda_k) \geq \frac{\eta}{2} \). Let \( V \) denote the neighborhood of \( \Upsilon \) of size \( 2\bar{\sigma} \). By the Hölder continuity of Dir-minimizing functions (cf. [3, Theorem 2.9]) there is a positive constant \( \vartheta > 0 \) such that \( |N_b^b(x)|^2 \geq 2\vartheta \) for every \( x \notin V \). We next introduce a parameter \( \sigma > 0 \) whose choice will be specified only at the very end: throughout the rest of the proof it will only required to be sufficiently small. In particular, \( \sigma < \bar{\sigma} \) will surely imply that

\[
\int_{B_{2\vartheta}(x)} |N_b^b|^2 \geq 2\vartheta \quad \forall \ x \in B_{\frac{3}{4}} \text{ with dist}(x, \Upsilon) \geq 4\bar{\sigma}.
\]

Therefore, from Theorem 6.2 we infer that, for sufficiently large \( k \)'s,

\[
\int_{B_{2\vartheta}(x)} G(\bar{N}_k, Q \left[ \eta \circ \bar{N}_k \right] )^2 \geq \vartheta h_k^2 \quad \forall \ x \in \Gamma_k := p_{\pi_k}(\Lambda_k).
\]

**Step 2.** For every \( p \in \Lambda_k \), consider \( \bar{z}_k(p) = p_{\pi_k}(p) \) (where \( \pi_k \) is the reference plane for the center manifold related to \( T_{(k)} \)) and \( \bar{x}_k(p) := (\bar{z}_k(p), \bar{r}_k^{-1}\varphi_{j(k)}(\bar{r}_k \bar{z}_k(p))) \). Observe that \( \bar{x}_k(p) \in \mathcal{M}_k \). We next claim the existence of a suitably chosen geometric constant \( c_0 > 0 \) (in particular, independent of \( \sigma \)) such that, when \( k \) is large enough, for each \( p \in \Lambda_k \) there is a radius \( \rho_p \leq 2\sigma \) with the following properties:

\[
\frac{c_0 \vartheta}{\sigma^\alpha} h_k^2 \leq \frac{1}{\rho_p^{m-2+\alpha}} \int_{B_{\rho_p}(\bar{x}_k(p))} |D\bar{N}_k|^2,
\]

\[
B_{\rho_p}(\bar{x}_k(p)) \subset B_{4\rho_p}(p).
\]

In order to show this claim, fix such a point \( p \), consider the point \( q_k := \bar{r}_k p, \ z_k := \bar{r}_k \bar{z}_k(p) \) and \( x_k = \bar{r}_k \bar{x}_k(p) = (z_k, \varphi_{j(k)}(z_k)) \). Observe that \( q_k \in D_Q(T_{j(k)}) \). By [4, Proposition 3.1], \( z_k \) cannot belong to some \( L \in \mathcal{W}_j \) (otherwise \( B_{16\rho_p}(p_L) \) would contain a multiplicity \( Q \) point of \( T_{j(k)} \), contradicting statement (S1) in [4, Proposition 3.1]). We thus distinguish two possibilities:

(Exc) either \( z_k \) belongs to some \( L_k \in \mathcal{W}_e \cup \mathcal{W}_n \);

(Con) or it belongs to the set \( \Gamma_{j(k)} \).
Case (Exc). Observe that if $L_k \in \mathcal{W}^{e,j(k)}_\alpha$, by Proposition 2.2 (iii), there exists a cube $H_k \in \mathcal{W}^{e,j(k)}_\alpha$ such that $L_k$ belongs to the domain of influence of $H$ and $\text{sep}(B_{\tilde{r}_k}, H_k) \leq 3\tilde{r}_k/16$. Thus $H_k$ intersects $B_{19\tilde{r}_k/16}(0, \pi)$.

We wish now to apply [4, Proposition 3.5] to infer that
\[
\bar{\ell}_k := \tilde{r}_k^{-1} \sup \{\ell(L) : L \in \mathcal{W}^{e,j(k)}_\alpha\} \quad \text{and} \quad L \cap B_{19\tilde{r}_k/16}(0, \pi) \neq \emptyset = o(1). \tag{6.8}
\]

Observe in fact that $\mathcal{H}^{m-2+\alpha}(D_Q(T_{j(k)}), B_{\gamma \eta}) \geq C_0 \eta =: \bar{\alpha} > 0$ (where $C_0$ is a geometric factor) and thus for any fixed $\bar{\alpha}$, [4, Proposition 3.5] is applicable for $k$ large enough because of Lemma 6.1(i).

For $k$ large enough, we can then apply [4, Proposition 3.6] with $\eta_2 = \frac{\eta}{4}$ (in particular this condition on how large $k$ must be is independent of the point $p$). The Proposition will be applied to $L_k$, if $L_k \in \mathcal{W}^{e,j(k)}_\alpha$, or to $H_k$ above, if $L_k \in \mathcal{W}^{q,j(k)}_\alpha$. Therefore, there exists a constant $\bar{s} < 1$ such that
\[
\int_{B_{2\bar{s}t(L_k)}(\bar{x}_k)} \mathcal{G}(N_{j(k)}, Q \left[\eta \circ N_{j(k)}\right])^2 \leq \frac{\varrho}{4^{\mathcal{H}(L_k)^{m-2}}} \int_{B_{t(L_k)}(\bar{x}_k)} |DN_{j(k)}|^2,
\]
that is, rescaling to $\mathcal{M}_k$, there exists $t(p) \leq \bar{\ell}_k$ such that
\[
\int_{B_{2t(p)}(\bar{x}_k(p))} \mathcal{G}(\bar{\mathcal{N}}_k, Q \left[\eta \circ \bar{\mathcal{N}}_k\right])^2 \leq \frac{\varrho}{4^{\mathcal{H}(p)^{m-2}}} \int_{B_{t(p)}(\bar{x}_k(p))} |D\bar{\mathcal{N}}_k|^2. \tag{6.9}
\]

By (6.8) we can assume that, provided $k$ is large enough, then $t(p) = \frac{\ell(L)}{\tilde{r}_k} \leq \bar{\ell}_k \leq \sigma$. Moreover, from Proposition 2.2 (v) and Lemma 6.1, for $k$ large enough, we get
\[
|p - \bar{x}_k(p)| \leq C(m_{0}^{j(k)}) \frac{1}{\bar{m}} p^\beta t(p) < \bar{s} t(p). \tag{6.10}
\]

Case (Con). In case $q_k$ belongs to the contact set $\Phi_{j(k)}(\Gamma_{j(k)})$, then $p = x_k(p)$ and $N_{j(k)}(x_k(p)) = Q[0]$. Therefore
\[
\lim_{t \downarrow 0} \int_{B_t(x_k(p))} \mathcal{G}(\bar{\mathcal{N}}_k, Q \left[\eta \circ \bar{\mathcal{N}}_k\right])^2 = 0
\]
and we choose $t(p) < \sigma$ such that
\[
\int_{B_{2t(p)}(x_k(p))} \mathcal{G}(\bar{\mathcal{N}}_k, Q \left[\eta \circ \bar{\mathcal{N}}_k\right])^2 \leq \frac{\varrho}{4} h_k^2. \tag{6.11}
\]

Observe also that (6.10) holds trivially.

Having chosen $t(p)$ in both cases, we next show the existence of $\varrho_p \in ]\bar{s} t(p), 2\sigma[\] such that (6.7) holds. Observe that (6.7) will be an obvious consequence of (6.10). Notice that if
\[
\frac{1}{\mathcal{H}(p)^{m-2}} \int_{B_{t(p)}(x_k(p))} |D\mathcal{N}_k|^2 \geq h_k^2, \tag{6.12}
\]
and (6.6) follows with $\varrho_p = t(p)$. If (6.12) does not hold, then
\[
\int_{B_{t(p)}(x_k(p))} \mathcal{G}(\bar{\mathcal{N}}_k, Q \left[\eta \circ \bar{\mathcal{N}}_k\right])^2 \leq \frac{\varrho}{4} h_k^2. \tag{6.13}
\]
Indeed we can use (6.9) in the case (Exc) (in the case (Con) we have already shown it: see (6.11)).

We now argue by contradiction to infer the existence of \( \varrho_p \in ]\bar{s}t(p), 2\sigma] \) such that (6.6) holds. Indeed, if this were not the case, setting for simplicity \( f := \mathcal{G}(\bar{N}_k, Q \left[ \Bar{\eta} \circ \bar{N}_k \right] ) \) and letting \( j \) be the smallest integer such that \( 2^{-j} \sigma \leq \bar{s}t(p) \), we can estimate as follows

\[
\int_{B_{2\sigma}(\bar{x}_k(p))} f^2 \leq 2 \int_{B_{3\sigma}(\bar{x}_k(p))} f^2 + \sum_{i=0}^{j} \left( \int_{B_{2^{i+1}\sigma}(\bar{x}_k(p))} f^2 - \int_{B_{2^{i}\sigma}(\bar{x}_k(p))} f^2 \right)
\]

\[
\overset{(6.13)}{=} \frac{\varrho}{2} h_k^2 + C \sum_{i=1}^{j} \frac{1}{(2^{-i}\sigma)^{m-2}} \int_{B_{2^{i+1}\sigma}(\bar{x}_k(p))} |D\bar{N}_k|^2
\]

\[
\leq \frac{\varrho}{2} h_k^2 + C c_0 \sum_{i=1}^{j} (2^{-i}\sigma)^{\alpha} \leq h_k^2 \left( \frac{\varrho}{2} + C(\alpha)c_0 \right).
\]

In the second line we have used the simple Morrey inequality

\[
\left| \int_{B_{2^{i+1}}(\bar{x}_k(p))} f^2 - \int_{B_{2^i}(\bar{x}_k(p))} f^2 \right| \leq \frac{C_0}{\varrho^{m-2}} \int_{B_{2^{i+1}}(\bar{x}_k(p))} |Df|^2 \leq \frac{C_0}{\varrho^{m-2}} \int_{B_{2^i}(\bar{x}_k(p))} |D\bar{N}_k|^2.
\]

The constant \( C_0 \) depends only upon the regularity of the underlying manifold \( \mathcal{M}_k \), and, hence, can assumed independent of \( k \).

Since \( C(\alpha) \) depends only on \( \alpha, m \) and \( Q \), for \( c_0 \) chosen sufficiently small the latter inequality would contradict (6.5). Note that (6.7) follows by a simple triangular inequality.

**Step 3.** Finally, we show that (6.6) and (6.7) lead to a contradiction. Consider a covering of \( \Lambda_k \) with balls \( B^i := B_{2\varrho p_i}(p_i) \) with the property that the corresponding balls \( B_{4\varrho p_i}(p_i) \) are disjoint. We then can estimate

\[
\frac{\eta}{2} \leq C_0 \sum_i \varrho_{p_i}^{m-2+\alpha} \leq C_0 \frac{\sigma^\alpha}{c_0 \varrho h_k^2} \int_{B_{\varrho p_i}(\bar{x}_k(p_i))} |D\bar{N}_k|^2
\]

\[
\overset{(6.6)}{=} \frac{C_0}{\varrho} \frac{\sigma^\alpha}{h_k^2} \int_{B_{\frac{\eta}{2}}} |D\bar{N}_k|^2 \overset{(6.4)}{=} C \frac{\sigma^\alpha}{\varrho},
\]

where \( C_0 > 0 \) is a dimensional constant. In the last line we have used that, thanks to (6.7), the balls \( B_{\varrho p_i}(p_i) \) are pairwise disjoint and that, provided \( \sigma \) is smaller than \( \frac{1}{32} \) and \( k \) large enough, they are all contained in \( B_{\frac{\eta}{2}} \). Since \( \varrho \) and \( c_0 \) are independent of \( \sigma \), the above inequality reaches the desired contradiction as soon as \( \sigma \) is fixed sufficiently small. This will only require a sufficiently small \( \bar{k} \), which by (6.8) is ensured for \( k \) sufficiently large.

7. **Harmonicity of the limit**

In this section we prove Theorem 6.2 and conclude our argument. We continue to follow the notation of the previous section, in particular recall the maps defined in (BU1) and (BU2) of Section 6.1.
7.1. First estimates. Without loss of generality we might translate the manifolds \( \tilde{M}_k \) so that the rescaled points \( \tilde{y}_k = \bar{r}_k^{-1} \Phi_{j(k)}(0) \) coincide all with the origin. Let \( F_k : \mathcal{B}_{\frac{3}{2}} \subset \tilde{M}_k \to A_Q(\mathbb{R}^{m+n}) \) be the multiple valued map given by \( \bar{F}_k(x) := \sum_i \left[ x + (\tilde{N}_k)_i(x) \right] \) and, to simplify the notation, set \( p_k := p_{\tilde{M}_k} \). We start by showing the existence of a suitable exponent \( \gamma > 0 \) such that

\[
\text{Lip}(\tilde{N}_k|_{\mathcal{B}_{\frac{3}{2}}}) \leq C h_k^\gamma \quad \text{and} \quad C(p_k^{-1}(\mathcal{B}_{\frac{1}{2}})) \leq C m_0^{j(k)}(\bar{r}_k)^\gamma, \tag{7.1}
\]

\[
M((T_{\bar{r}_k} - T_k) \cup (p_k^{-1}(\mathcal{B}_{\frac{1}{2}}))) \leq C h_k^{2+2\gamma}, \tag{7.2}
\]

\[
\int_{\mathcal{B}_{\frac{3}{2}}} |\eta \circ \tilde{N}_k| \leq C h_k^2. \tag{7.3}
\]

Indeed, set \( p_{j(k)} = \Phi_{j(k)}(0) \). Using the domain decomposition of Section 4.1 (note that \( \frac{3}{2} \bar{r}_k \in \mathcal{B}_{j(k)}(p_{j(k)}) \)) and arguing in an analogous way we infer that

\[
\| N_{j(k)} \|_{C^0(\mathcal{B}_{\frac{3}{2}}(p_{j(k)}))} \leq C m_0^{j(k)} \frac{1}{\bar{r}_k} \quad \text{and} \quad \text{Lip}(N_{j(k)}|_{\mathcal{B}_{\frac{3}{2}}(p_{j(k)})}) \leq C m_0^{j(k)} \max_i \ell_i^{\gamma_2},
\]

\[
M((T_{\bar{r}_k} - T_{j(k)}) \cup (p_k^{-1}(\mathcal{B}_{\frac{3}{2}}(p_{j(k)})))) \leq \sum_i (m_0^{j(k)})^{1+\gamma_2} \ell_i^{m_i+2+\gamma_2},
\]

\[
\int_{\mathcal{B}_{\frac{3}{2}}(p_{j(k)})} |\eta \circ N_{j(k)}| \leq C m_0^{j(k)} \bar{r}_k \sum_i \ell_i^{2+m_i+\gamma_2} + C h_k \int_{\mathcal{B}_{\frac{3}{2}}(p_{j(k)})} |N_{j(k)}|^2,
\]

where this time, for the latter inequality we have used [4, Theorem 2.4 (2.4)] with \( a = \bar{r}_k \).

On the other hand, by (3.17) and Corollary 5.3, we see that

\[
\sum_i m_0^{j(k)} \ell_i^{m_i+2+\gamma_2} \leq C_0 \int_{\mathcal{B}_{\frac{3}{2}}(p_{j(k)})} (|DN_{j(k)}|^2 + |N_{j(k)}|^2) \leq C \bar{r}_k^{-2} \int_{\mathcal{B}_{\frac{3}{2}}(p_{j(k)})} |N_{j(k)}|^2, \tag{7.4}
\]

from which (7.1)-(7.3) follow by a simple rescaling (the constant \( C \) on the right hand side of (7.4) depends on \( T \) but not on \( k \)).

It is then clear that the strong \( L^2 \) convergence of \( N^b_k \) is a consequence of these bounds and of the Sobolev embedding (cf. [3, Proposition 2.11]); whereas, by (7.3),

\[
\int_{\mathcal{B}_{\frac{3}{2}}} |\eta \circ N^b_\infty| = \lim_{k \to +\infty} \int_{\mathcal{B}_{\frac{3}{2}}} |\eta \circ N_k^b| \leq C \lim_{k \to +\infty} h_k = 0.
\]

Finally, note that \( N^b_\infty \) must take its values in \( \{0\} \times \mathbb{R}^n \times \{0\} \). Indeed, considering the tangential part of \( \tilde{N}_k \) given by \( \tilde{N}_k^T(x) := \sum_i \left[ p_{T_k \Sigma_k}(\tilde{N}_k(x)) \right]_i \), it is simple to verify that \( G(\tilde{N}_k, \tilde{N}_k^T) \leq C_0 |\tilde{N}_k|^2 \), which leads to

\[
\int_{\mathcal{B}_{\frac{3}{2}}} G(N^b_k, h_k^{-1} \tilde{N}_k^T \circ e_k)^2 \leq C_0 h_k^{-2} \int_{\mathcal{B}_{\frac{3}{2}}} |\tilde{N}_k|^4 \leq C (m_0^{j(k)} \bar{r}_k)^{2\gamma} \to 0 \quad \text{as} \quad k \to +\infty,
\]

and, by the convergence of \( \Sigma_k \) to \( \mathbb{R}^{m+n} \times \{0\} \), gives the claim.
7.2. A suitable trivialization of the normal bundle. By Lemma 6.1, we can consider for every $\mathcal{M}_k$ an orthonormal frame of $(T\mathcal{M}_k)^\perp$, $\nu^k_1, \ldots, \nu^k_m, \omega^k_1, \ldots, \omega^k_i$ with the property that $\nu^k_j(x) \in T_x\Sigma_k$, $\omega^k_j(x) \perp T_x\Sigma_k$ and (cf. [5, Lemma A.1])

$$\nu^k_j \to e_{m+j} \quad \text{and} \quad \omega^k_j \to e_{m+n+j} \quad \text{in } C^{2,\alpha/2}(\mathcal{M}_k) \text{ as } k \uparrow \infty$$

(for every $j$: here $e_0, \ldots, e_{m+n+l}$ is the standard basis of $\mathbb{R}^{m+n+l} = \mathbb{R}^{m+n}$). We next claim the existence of maps $\psi_k : \tilde{\mathcal{M}}_k \times \mathbb{R}^n \to \mathbb{R}^l$ converging to $0$ in $C^{2,\alpha}$ uniformly bounded in $C^{2,\alpha}$ and of $\delta > 0$ (independent of $k$) such that, for every $v \in T_p\mathcal{M}_k$ with $|v| \leq \delta$,

$$p + v \in \Sigma_k \iff v^\perp = \psi_k(p, v^T),$$

with $v^T = (\langle v, \nu^k_1 \rangle, \ldots, \langle v, \nu^k_m \rangle) \in \mathbb{R}^n$ and $v^\perp = (\langle v, \omega^k_1 \rangle, \ldots, \langle v, \omega^k_i \rangle) \in \mathbb{R}^l$. To see this, consider the map

$$\Phi_k : \tilde{\mathcal{M}}_k \times \mathbb{R}^n \times \mathbb{R}^l \ni (p, z, w) \mapsto p + z^j \nu^k_j + w^i \omega^k_i \in \mathbb{R}^{m+n},$$

where we use the Einstein convention of summation over repeated indices. It is simple to show that the frame can be chosen so that $D\Phi_k(0, 0) = \text{Id}$ and, hence, $\Phi_k^{-1}(\Sigma_k)$ can be written locally as a graph of a function $\psi_k$ satisfying the claim above.

Note that, by construction we also have that $\psi_k(p, 0) = |D_w\psi_k(p, 0)| = 0$ for every $p \in \mathcal{M}_k$, which in turn implies

$$|D_x\psi_k(x, w)| \leq C|w|^{1+\alpha}, \quad |D_w\psi_k(x, w)| \leq C|w| \quad \text{and} \quad |\psi_k(x, w)| \leq C|w|^2. \quad (7.5)$$

Given now any $Q$-valued map $u = \sum_i \|u_i\| : \tilde{\mathcal{M}}_k \to A_Q(\{0\} \times \mathbb{R}^n \times \{0\})$ with $\|u\|_{L^\infty} \leq \delta$, we can consider the map $u_k := \psi_k(x, u)$ defined by

$$x \mapsto \sum_i \left[ (u_i)^j \nu^k_j(x) + \psi_i^k(x, u_i(x))\omega^k_j(x) \right],$$

where we set $(u_i)^j := \langle u_i(x), e_{m+j} \rangle$, $\psi_i^k(x, u_i(x)) := \langle \psi_k(x, u_i(x)), e_{m+n+j} \rangle$ (again we use Einstein’s summation convention). Then, the differential map $Du_k := \sum_i [D(u_k)_i]$ is given by

$$Du_k_i = D(u_i)^j \nu^k_j + [D_x\psi_k^j(x, u_i) + D_w\psi_k^j(x, u_i)Du_i] \omega^k_j + (u_i)^j Du^k_j + \psi_i^k(x, u_i)D\omega^k_j.$$

Taking into account that $\|D\nu^k_j\|_{C^0} + \|D\omega^k_j\|_{C^0} \to 0$ as $k \to +\infty$, by (7.5) we deduce that

$$\int \left( |Du_k|^2 - |Du|^2 \right) \leq C \int \left( |Du|^2 |u| + |Du||u|^{1+\alpha} + |u|^{2+2\alpha} \right) + o(1) \int \left( |u|^2 + |Du|^2 \right).$$

(7.6)

Now we clearly have $N_k(x) = \psi_k(x, \tilde{u}_k)$ for some Lipschitz $\tilde{u}_k : \tilde{\mathcal{M}}_k \to A_Q(\mathbb{R}^n)$ with $\|\tilde{u}_k\|_{L^\infty} = o(1)$ by (7.1). Setting $u_k^b := \tilde{u}_k \circ e_k$, we conclude from (5.6), (7.1) and (7.6) that

$$\lim_{k \to +\infty} \int_{B_{\frac{1}{2}}} \left( |DN_k^b|^2 - h_k^2 |Du_k^b|^2 \right) = 0,$$

and $N^\infty_k$ is the limit of $h_k^{-1}u_k^b$.  

7.3. Competitor function. We now show the Dir-minimizing property of $N^b_\infty$. Clearly, there is nothing to prove if its Dirichlet energy vanishes. We can therefore assume that there exists $c_0 > 0$ such that

$$c_0 h_k^2 \leq \int_{B_2} |D\tilde{N}_k|^2.$$  (7.8)

Assume there is a radius $t \in \left] \frac{3}{4}, \frac{3}{2} \right]$ and a function $f : B_2 \to A_Q(\mathbb{R}^n)$ such that

$$f|_{B_2 \setminus B_t} = N^b_\infty|_{B_2 \setminus B_t} \quad \text{and} \quad \text{Dir}(f, B_t) \leq \text{Dir}(N^b_\infty, B_2) - 2 \delta,$$

for some $\delta > 0$. We can apply [6, Proposition 3.5] to the functions $h_k^{-1}u_k^b$ and find $r \in \left] t, 2 \right]$ and competitors $v_k^b$ such that, for $k$ large enough,

$$v_k^b|_{\partial B_r} = u_k^b|_{\partial B_r}, \quad \text{Lip}(v_k^b) \leq C h_k^\gamma, \quad |v_k^b| \leq C (m_{0, \bar{r}_k})^\gamma,$$

$$\int_{B_2^3} |\eta \circ v_k^b| \leq C h_k^2 \quad \text{and} \quad \int_{B_2} |Dv_k^b|^2 \leq \int_{B_2} |Du_k^b|^2 - \delta h_k^2,$$

where $C > 0$ is a constant independent of $k$ and $\gamma$ the exponent of (7.1)-(7.3). Clearly, by Lemma 6.1 and (7.5), the maps $\tilde{N}_k = \psi_k(x, v_k^b \circ e_k^{-1})$ satisfy

$$\tilde{N}_k \equiv \bar{N}_k \quad \text{in} \quad B_2 \setminus B_t, \quad \text{Lip}(\tilde{N}_k) \leq C h_k^\gamma, \quad |\tilde{N}_k| \leq C (m_{0, \bar{r}_k})^\gamma,$$

$$\int_{B_2^3} |\eta \circ \tilde{N}_k| \leq C h_k^2 \quad \text{and} \quad \int_{B_2} |D\tilde{N}_k|^2 \leq \int_{B_3^3} |D\tilde{N}_k|^2 - \delta h_k^2.$$

7.4. Competitor current. Consider finally the map $\bar{F}_k(x) = \sum_i [x + \tilde{N}_i(x)]$. The current $T_{\bar{F}_k}$ coincides with $T_{\bar{F}_k}$ on $p_k^{-1}(B_2 \setminus B_t)$. Define the function $\varphi_k(p) = \text{dist}_{\bar{X}_k}(0, p_k(p))$ and consider for each $s \in \left] t, \frac{3}{2} \right[$ the slices $(T_{\bar{F}_k} - T_k, \varphi_k, s)$. By (7.2) we have

$$\int_t^{\bar{r}_k} M(\langle T_{\bar{F}_k} - T_k, \varphi_k, s \rangle) \leq C h_k^{2+\gamma}.$$  (7.9)

Thus we can find for each $k$ a radius $\sigma_k \in \left] t, \frac{3}{2} \right]$ on which $M(\langle T_{\bar{F}_k} - T_k, \varphi_k, \sigma_k \rangle) \leq C h_k^{2+\gamma}$. By the isoperimetric inequality (see [6, Remark 4.3]) there is a current $S_k$ such that

$$\partial S_k = \langle T_{\bar{F}_k} - T_k, \varphi_k, \sigma_k \rangle, \quad M(S_k) \leq C h_k^{2+\gamma}\frac{m(m-1)}{m} \quad \text{and} \quad \text{spt}(S_k) \subset \bar{\Sigma}_k.$$

Our competitor current is, then, given by

$$Z_k := T_k \cup (p_k^{-1}(\bar{M}_k \setminus B_{\sigma_k})) + S_k + T_{\bar{F}_k} \cup (p_k^{-1}(B_{\sigma_k})).$$

Note that $Z_k$ is supported in $\bar{\Sigma}_k$ and has the same boundary as $T_k$. On the other hand, by (7.2) and the bound on $M(S_k)$, we have

$$M(T_k) - M(T_{\bar{F}_k}) \leq M(T_{\bar{F}_k} - T_k) + C h_k^{2+2\gamma}.$$  (7.9)
Denote by $A_k$ and by $H_k$ respectively the second fundamental forms and mean curvatures of the manifolds $\mathcal{M}_k$. Using the Taylor expansion of [5, Theorem 3.2], we achieve

$$M(\mathcal{T}_k) - M(\mathcal{\bar{T}}_k) \leq \frac{1}{2} \int_{\mathcal{S}_k} \left(|D\mathcal{N}_k|^2 - |D\mathcal{N}_k|\right)^2 + C\|H_k\|c^0 \int \left(|\eta \circ \mathcal{N}_k| + |\eta \circ \mathcal{N}_k|\right)^2 + \|A_k\|c^0 \int \left(|\mathcal{N}_k|^2 + |\mathcal{N}_k|^2\right)^2 + o(h_k^2) \leq -\frac{\delta}{2} h_k^2 + o(h_k^2), \quad (7.10)$$

where in the last inequality we have taken into account Lemma 6.1. Clearly, (7.10) and (7.9) contradict the minimizing property of $\mathcal{\bar{T}}_k$ for $k$ large enough and concludes the proof.

**Appendix A. Some Technical Lemmas**

The following is a special case of Allard’s $\varepsilon$-regularity theory (see [10, Chapter 5]).

**Theorem A.1.** Assume $T$ is area minimizing, $x \in D_Q(T)$ and $\|T\|((\text{spt}(T) \cap U) \setminus D_Q) = 0$ in some neighborhood $U$ of $x$. Then, $x \in \text{Reg}(T)$. In particular, $D_1(T) \subset \text{Reg}(T)$.

**Proof.** By simple considerations on the density, the tangent cones at $x$ must necessarily be all $m$-dimensional planes with multiplicity $Q$. This allows to apply Allard’s theorem and conclude that, in a neighborhood of $x$, $\text{spt}(T)$ is necessarily the graph of a $C^{1,\kappa_0}$ function for some $\kappa_0 > 0$. Let $u : \mathbb{R}^m \to \mathbb{R}^{n+l}$ be the corresponding function and $\Psi : \mathbb{R}^{m+n} \to \mathbb{R}^l$ a $C^{3,\kappa_0}$ function whose graph describes $\Sigma$. Let $\mathcal{\tilde{u}}$ consist of the first $\tilde{n}$ coordinates functions of $u$. We then have that $\mathcal{\tilde{u}}$ minimizes an elliptic functional of the form $\int \Phi(x, \mathcal{\tilde{u}}(x), D\mathcal{\tilde{u}}(x)) \, dx$ where $(x, v, p) \mapsto \Phi(x, v, p)$ and $(x, v, p) \to D_p \Phi(x, v, p)$ are of class $C^{2,\kappa_0}$.

We can then apply the classical regularity theory to conclude that $\mathcal{\tilde{u}} \in C^{3,\kappa_0}$ (see, for instance, [9, Theorem 9.2]), thereby concluding that $x$ belongs to $\text{Reg}(T)$ according to Definition 0.2. Fix next any $x \in D_1(T)$. By the upper semicontinuity of the density $\Theta$ (cp. [10]), $\Theta \leq \frac{3}{2}$ in a neighborhood $U$ of $x$, which implies $\|T\|((\text{spt}(T) \cap U) \setminus D_1) = 0$. \hfill \Box

Next, we prove the following technical lemma.

**Lemma A.2.** Let $T$ be an integer rectifiable current of dimension $m$ in $\mathbb{R}^{m+n}$ with locally finite mass and $U$ an open set such that $\mathcal{H}^{m-1}(\partial U \cap \text{spt}(T)) = 0$ and $(\partial T) \cap U = 0$. Then $\partial(T \cap U) = 0$.

**Proof.** Consider $V \subset \subset \mathbb{R}^{m+n}$. By the slicing Theorem [7, 4.2.1] applied to $\text{dist}(\cdot, \partial U)$ we conclude that $S_r := T\mathcal{\mathcal{L}}(V \cap U \cap \{\text{dist}(x, \partial U) > r\})$ is a normal current in $N_m(V)$ for a.e. $r$. Since $M(T\mathcal{\mathcal{L}}(V \cap U) = S_r) \to 0$ as $r \downarrow 0$, we conclude that $T\mathcal{\mathcal{L}}(U \cap V)$ is in the $M$-closure of $N_m(V)$. Thus, by [7, 4.1.17], $T\mathcal{\mathcal{L}}U$ is a flat chain in $\mathbb{R}^{m+n}$. By [7, 4.1.12], $\partial(T\mathcal{\mathcal{L}}U)$ is also a flat chain. It is easy to check that $\text{spt}(\partial(T\mathcal{\mathcal{L}}U)) \subset \partial U \cap \text{spt}(T)$. Thus we can apply [7, Theorem 4.1.20] to conclude that $\partial(T\mathcal{\mathcal{L}}U) = 0$. \hfill \Box

Recall the following theorem (for the proof see [10, Theorem 35.3]).

**Theorem A.3.** If $T$ is an integer rectifiable area minimizing current in $\Sigma$, then

$$\mathcal{H}^{m-3+\alpha}_{\infty}\left(\text{spt}(T) \setminus \left(\text{spt}(\partial T) \cup \bigcup_{Q \in \mathbb{N}} D_Q(T)\right)\right) = 0 \quad \forall \alpha > 0.$$
We finally prove the following result (first proved by Allard in an unpublished note and hence reported in [1]).

**Proposition A.4.** Set \( \pi := \mathbb{R}^m \times \{0\} \subset \mathbb{R}^{m+n} \) and let \( \mathcal{M} \) be the graph of a \( C^{3,\kappa} \) function \( \varphi : \pi \supset B_3(0) \rightarrow \mathbb{R}^m \), with \( \varphi(0) = 0 \). Then the exponential map \( \exp : B_3(0) \rightarrow \mathcal{M} \) belongs to the class \( C^{2,\kappa} \). Moreover, if \( \|\varphi\|_{C^{3,\kappa}} \) is sufficiently small, then the set \( p_\pi(\exp(B_r(0))) \subset \pi \) is (for all \( r < 3 \)) a convex set and the maximal curvature of its boundary is less than \( \frac{2}{r} \).

**Proof.** Consider any \( C^{3,\kappa} \) chart \( x : \mathcal{M} \rightarrow \Omega \), for instance the one induced by the graphical structure. It is then obvious that the components \( g_{ij} \) of the Riemannian metric (induced by the Euclidean ambient space on the submanifold \( \mathcal{M} \)) are \( C^{2,\kappa} \). We let \( \nabla \) be the Levi-Civita connection on \( \mathcal{M} \) for which \( g \) is parallel and consider the corresponding Christoffel symbols \( \Gamma^i_{jk} \) (in the fixed coordinate patch). Using the standard formula which expresses the Christoffel symbols \( \Gamma^i_{jk} \) in terms of the metric \( g_{sr} \) (see for instance [8, Proposition 2.54]), it is easy to see that the former are \( C^{1,\kappa} \). The careful reader will notice that these objects are usually defined in standard textbooks assuming that the metric is \( C^\infty \), but in order to have a unique Levi-Civita connection it is enough that the metric is \( C^1 \), see the proof of [8, Theorem 2.51] (in fact the Levi-Civita connection on \( \mathcal{M} \) can also be recovered by differentiating in the Euclidean ambient space and projecting the result onto the tangent space to \( \mathcal{M} \)). Similarly, for \( C^2 \) metrics we can use the intrinsic definition of the Riemann curvature tensor as in [8, Definition 3.3]. From the standard formula in [8, 3.16] we easily conclude that the components of this tensor are \( C^{0,\kappa} \). However, by [3, Lemma A.1] we can choose a \( C^{2,\kappa} \) orthonormal frame \( \nu_1, \ldots, \nu_n : \Omega \rightarrow \mathbb{R}^{m+n} \) for the normal bundle of \( \mathcal{M} \) and the curvature tensor can be computed via the Gauss' equations as in [8, 5.8b]): we thus conclude that the components of the Riemann tensor are in fact \( C^{1,\kappa} \). Again, although the references above carry on all computations in the \( C^\infty \) setting, it can be easily checked that these work in a straightforward way under our regularity assumptions.

Let next \( \Phi(t, v) := \exp(v t) \) (the fact that the exponential map is well defined will be justified in few lines). Fix a \( C^{3,\kappa} \) coordinate patch on \( \mathcal{M} \) where \( 0 \) is the origin, using the graphical structure of \( \mathcal{M} \) over \( T_0 \mathcal{M} \). Set \( t \mapsto \gamma(t) = \Phi(t, v) \) and use the notation \( \gamma'_j \) for the components of \( \gamma' \) in the fixed chart \( x : \Omega \rightarrow \mathcal{M} \) (so, \( \gamma'(t) = \sum_j \gamma'_j(t) \frac{\partial}{\partial x_j} \)). \( \gamma \) satisfies the system of differential equations

\[
\gamma''_j(t) + \sum_{ik} \Gamma^l_{jk}(\gamma(t)) \gamma'_l(t) \gamma'_k(t) = 0,
\]

with the initial conditions \( \gamma(0) = 0 \) and \( \gamma'(0) = v \), cf. [8, Definition 2.77]. It follows thus that the maps \( \Phi \) and \( \partial_t \Phi \) are \( C^{1,\kappa} \); incidentally, this shows that the exponential map is well-defined (in fact, standard textbooks on ODEs only provide \( C^1 \) regularity; however the usual proof of \( C^1 \) regularity via Gronwall Lemma on the linearized ODEs for the derivative \( \partial_v \Phi \) can be easily modified to prove \( \partial_v \Phi \in C^{0,\kappa} \); cf. [2, Section 9]).

Fix now a tangent vector \( e \) at \( 0 \), a point \( p = \exp(v) \in \mathcal{M} \) and perform a parallel transport of \( e \) along the (“radial”) geodesic segment \( [0, 1] \ni t \mapsto \exp(tv) \) to define \( e(p) \). We claim that the corresponding vector field is \( C^{1,\kappa} \). Indeed, fix any orthonormal tangent
frame \( f_1, \ldots, f_m \) which is \( C^{2,\kappa} \). Let
\[
e(\exp(tv)) = \sum_i \alpha_{v,i}(t) f_i(\Phi(t,v)) = \sum_{i,k} \alpha_{v,i}(t) \sum_k \varphi_{ik}(\Phi(t,v)) \frac{\partial}{\partial x_k},
\]
where the functions \( \varphi_{ik} \) are \( C^{2,\kappa} \). Recall that the a vector field \( X(t) = \sum_j X_j(t) \frac{\partial}{\partial x_j} \) along a \( C^1 \) curve \( c \) with tangent \( c'(t) = \sum_i c'_i(t) \frac{\partial}{\partial x_i} \) is parallel if and only if
\[
X'_i(t) = -\sum_{j,k} \Gamma^i_{jk}(c(t)) c'_j(t) X_k(t),
\]
cf. [8, Theorem 2.68 and equation (2.69)]. We therefore conclude that the coefficients \( \alpha_{v,i}(t) \) must satisfy a system of ODEs of the form
\[
\alpha'_{v,i}(t) = -\sum_j \alpha_{v,j}(t) F_{ij}(\Phi(t,v), \partial_t \Phi(t,v))
\]
where \( (t, v) \mapsto F_{ij}(\Phi(t,v), \partial_t \Phi(t,v)) \) are \( C^{1,\kappa} \) maps. Thus the existence of \( e \) and the claimed regularity of \( (t, v) \mapsto \alpha_{v,i}(t) \) follow from the standard theory of ODEs.

Recall also that the parallel transport keeps the angle between vectors constant, cf. [8, Proposition 2.74]. We conclude that there exists an orthonormal frame \( e_1, \ldots, e_m \) of class \( C^{1,\kappa} \) which is parallel along geodesic rays emanating from the origin. Next, consider the map \( (w, v, t) \mapsto \partial_w \Phi(t,v) \) where \( w \) varies in \( \mathbb{R}^m \). Fix \( w \) and \( v \) and consider again the curve \( \gamma(t) \) above and the vector \( \eta_{v,w}(t) = \partial_w \Phi(t,v) \). We claim that \( \eta \) satisfies the Jacobi equation along the geodesic \( \gamma \), with initial data \( \eta_{v,w}(0) = 0 \) and \( \eta'_{v,w}(0) = w \). More precisely, if we write the vector field in the frame \( e_i \) as \( \eta(t) = \sum_i \eta_i(t)e_i(\gamma(t)) \), the Jacobi equation is
\[
\eta''_{v,w,i}(t) = -\sum_j R_{\gamma(t)}(e_j(\gamma(t)), \gamma'(t), \gamma''(t), e_i(\gamma(t))) \eta_{v,w,j}(t), \tag{A.1}
\]
where \( R \) depends on the Riemann tensor (cf. [8, Theorem 3.43]). Note that we do not have the usual smoothness assumptions under which (A.1) is derived in standard textbooks. We can however proceed by regularizing our manifold \( M \) via convolution of the function of which the manifold is a graph. We fix the corresponding graphical charts for the regularized manifolds and observe that the exponential maps in these coordinates have uniform \( C^{1,\kappa} \) bounds from the corresponding ODEs and thus will converge to \( \Phi \) in \( C^1 \). Similarly one concludes the obvious convergence statements for the Riemann tensor and thus the right hand side of (A.1) for the corresponding objects converge uniformly. This justifies, in the limit, that \( \eta_{v,w,i} \) is twice differentiable (in time) and that (A.1) holds.

Taking into account that \( \gamma(t) = \Phi(t,v) \) and \( \gamma'(t) = \partial_t \Phi(t,v) \) we conclude that \( \eta_{v,w,i} \) satisfies an ODE of the type \( \eta''_{v,w,i}(t) = \Lambda(t,v, \eta_{v,w,i}(t)) \) where the function \( \Lambda \) is \( C^{1,\kappa} \) in all its entries. We thus conclude that the map \( (v, w, t) \mapsto \eta_{v,w}(t) = \partial_w \Phi(t,v) \) is a \( C^{1,\kappa} \) map. Since \( d \exp(v)(w) = \partial_w \Phi(v,1) \), this implies that the exponential map is \( C^{2,\kappa} \).

As for the last assertion, for \( \|\varphi\|_{C^{2,\kappa}} \) sufficiently small we conclude from the discussion above that \( p_\pi \circ \exp \) is \( C^2 \) close to the identity, which implies the desired statement. \( \square \)
