

HÖLDER REGULARITY FOR NONLOCAL DOUBLE PHASE EQUATIONS

CRISTIANA DE FILIPPIS AND GIAMPIERO PALATUCCI

ABSTRACT. We prove some regularity estimates for viscosity solutions to a class of possible degenerate and singular integro-differential equations whose leading operator switches between two different types of fractional elliptic phases, according to the zero set of a modulating coefficient $a = a(\cdot, \cdot)$. The model case is driven by the following nonlocal double phase operator,

$$\int \frac{|u(x) - u(y)|^{p-2}(u(x) - u(y))}{|x - y|^{n+sp}} dy + \int a(x, y) \frac{|u(x) - u(y)|^{q-2}(u(x) - u(y))}{|x - y|^{n+sq}} dy,$$

where $q \geq p$ and $a(\cdot, \cdot) \geq 0$. Our results do also apply for inhomogeneous equations, for very general classes of measurable kernels. By simply assuming the boundedness of the modulating coefficient, we are able to prove that the solutions are Hölder continuous, whereas similar sharp results for the classical local case do require a to be Hölder continuous. To our knowledge, this is the first (regularity) result for nonlocal double phase problems.

1. NONLOCAL DOUBLE PHASE PROBLEMS

We deal with nonlocal *double phase equations*; that is, a class of, possible singular and degenerate, integro-differential equations whose leading operator switches between two different fractional elliptic phases according to the zero set of the *modulating coefficient* $a = a(\cdot, \cdot)$. These equations are indeed driven by the following nonlocal double phase operator,

$$(1.1) \quad \mathcal{L}(u) := P.V. \int_{\mathbb{R}^n} |u(x) - u(y)|^{p-2} (u(x) - u(y)) K_{sp}(x, y) dy \\ + P.V. \int_{\mathbb{R}^n} a(x, y) |u(x) - u(y)|^{q-2} (u(x) - u(y)) K_{tq}(x, y) dy, \quad x \in \mathbb{R}^n,$$

where the involved kernels $K_{sp}, K_{tq} : \mathbb{R}^n \times \mathbb{R}^n \rightarrow (0, \infty)$ are measurable functions of differentiability orders $s, t \in (0, 1)$ and summability exponents $p, q \in (1, \infty)$, respectively. Here *P.V.* stands for the principal value. We immediately refer to Section 2 for the precise assumptions on the involved quantities in the general framework we are considering. In order to simplify, one can just keep in mind the model case when the kernels K_{sp} and K_{tq} do coincide with the Gagliardo kernels $|x - y|^{-n-sp}$ and $|x - y|^{-n-tq}$, respectively; i. e., the case when the corresponding operator \mathcal{L} does reduce to a sum of a pure p -fractional Laplacian $(-\Delta)_p^s$ and an integro-differential operator whose (t, q) -kernel is perturbed by the modulating coefficient $a(\cdot, \cdot)$.

Such a case can be plainly seen as the nonlocal analog of the classical double phase problems, whose chief model is related to by the following energy functional,

$$(1.2) \quad \mathcal{F}(u) := \int \left(|Du|^p + a(x)|Du|^q \right) dx, \quad 1 < p \leq q,$$

naturally defined for Sobolev functions. The functional \mathcal{F} originally arose in Homogenization Theory and it is related to the so-called Lavrentiev phenomenon; see for instance [37, 38]. From a regularity point of view, even without the presence of the modulating coefficient $a(\cdot)$, such functional presents very interesting features, falling in the class of the non-uniformly elliptic ones having (p, q) -growth conditions. Thus, it cannot be treated via the standard available regularity methods; we refer the reader to the pioneering work by Marcellini [27–30], where the fundamentals of the (p, q) -regularity theory have been settled. One of the main points in the important (p, q) -theory is the lack of regularity results for more general functionals whose integrand depends on x possibly in a non-smooth way. In this respect, in view of the presence of the modulating coefficient, the functional \mathcal{F} in (1.2) is conceivably the prototype of the worst kind of interplay between the coefficient in x and the (p, q) -growth, since it clearly brings a change of ellipticity/growth occurring on the set $\{a = 0\}$. Let us consider the significant case when $q > p$: in the points where $a > 0$ the functional \mathcal{F} reduces to a non-standard (p, q) -growth functional, which exhibits a q -growth in the gradient. On the contrary, in the points where $a = 0$ the functional exhibits a p -growth in the gradient. This is the main feature of this class of functionals and it is basically the reason why they have been firstly introduced by Zhikov in the aforementioned papers in order to describe the behavior of strongly

anisotropic materials whose hardening properties drastically change with the point. Such an important phase-transition problem is thus described by the functional \mathcal{F} , where the regulation of the mixture between two different materials, with p and q hardening, is modulated by the coefficient $a(\cdot)$, which simultaneously brought new difficulties in the corresponding regularity theory. Indeed, even basic regularity issues for these double phase problems have remained unsolved for several decades. The first result in this spirit was recently due to Colombo and Mingione in [11], where, amongst other achievements, they proved *Hölder continuity for the weak solutions by assuming that the modulating coefficient $a(\cdot)$ is Hölder continuous as well*. This important result is also proven to be sharp both with respect to the Hölder continuity assumption on the modulating coefficient and with respect to the result obtained. See in particular Theorem 1.1 in [11], and also Remarks 1-3 in forthcoming Section 2 and Section 5.2 for a discussion about the restriction on the involved quantities.

Starting from the work of Colombo and Mingione, despite its relatively short history, double phase problems have already evolved into an elaborate theory with several connections to other branches; the literature is too wide to attempt any comprehensive treatment in a single paper. We refer, for instance, to [2, 3, 7, 12–14, 25, 34] and the references therein.

Let us come back to the equations we are dealing with. In the present paper, we consider the nonlocal version of the double phase problems described above. More in general, we also consider inhomogeneous equations with a given datum $f \in L^\infty_{\text{loc}}$. Our main result reads as follows:

(1.3) *Suppose that the modulating coefficient $a(\cdot, \cdot)$ is such that $0 \leq a \leq M$,*

(1.4) *then any bounded viscosity solution u to $\mathcal{L}u = f$ is locally Hölder continuous.*

For the precise assumptions and statement, we refer to forthcoming Section 2, and in particular to Theorem 1 there.

Now, a few observations are in order:

- First of all, in contrast with respect to the local case, we are able to prove that (viscosity) solutions to the fractional analog of double phase equations are Hölder continuous by simply assuming the boundedness of the modulating coefficients $a(\cdot, \cdot)$. In the corresponding local case, the $C^{1,\beta}$ -regularity result by Colombo and Mingione is crucially related to the absence of the Lavrentiev phenomenon. This is achieved provided that the ratio q/p is suitably bounded, i.e.: $1 \leq q/p \leq 1 + \alpha/p$, where the $\alpha \in (0, 1]$ is the Hölder exponent of $a(\cdot)$; see [12, Proposition 3.6] and also the related preliminary result for what concerns the analysis of the Lavrentiev effect in [18]. Analogously, the much weaker assumption $a \in L^\infty$ in (1.3) may be interpreted as an ineffectiveness of the Lavrentiev phenomenon in the nonlocal framework, and a consequent assumption on the differentiability exponents (s, t) and summability ones (p, q) will appear in accordance with the local results.

- Second, the equation in (1.4) inherits both the difficulties newly arising from the double phase problems and those naturally arising from the nonlocal character

of the involved fractional integro-differential operators. More than this, it is worth noticing that the fractional operators \mathcal{L} in (1.1) present as well the typical issues given by their *nonlinear* growth behavior, and further efforts are needed due to the presence of merely measurable coefficients in the kernels K_{sp}, K_{tq} . For this, some very important tools recently introduced in the nonlocal theory, as the celebrated Caffarelli-Silvestre s -harmonic extension [8], and other minor successful tricks, as for instance the pseudo-differential commutator compactness in [32] or the energy density estimates in [10, 19, 33], seem not to be adaptable to the framework considered here.

- Third, to our knowledge, this is the very first regularity result for solutions to nonlocal double phase equations. Even in the very special case when both the differentiability orders and the summability exponents coincide; that is, when $s = t$ and $p = q$, no related results involving a modulating coefficient could be found in the literature; however, it is worth mentioning the fine Hölder estimates in the relevant paper [20], where the authors deal with a class of elliptic integro-differential operators with kernels satisfying lower bounds on conic subsets, thus strongly directionally dependent.

For what concerns our approach to attack the problem, we extend that in the by-now classical work by Silvestre in [36], where the author provides a surprisingly clean and purely analytical proof of Hölder continuity for harmonic functions with respect to a class of integro-differential equations like the fractional Laplace with coefficients. The approach developed by Silvestre also includes the case of variable orders, and it has been proven to be very feasible to attack several problems in the recent nonlocal theory, even in the case of the p -fractional Laplace equation, as seen in the recent paper by Lindgren [26]. Clearly, the mentioned approach cannot be plainly applied to the operator in (1.4) because our class of operators lives in the nonstandard (p, q) -growth setting, and, even worst, we have to take care of the novelty given by the presence of the modulating coefficient $a(\cdot, \cdot)$. In addition, it is worth mentioning that such non-uniform ellipticity together with the interplay of the two differentiability orders via the modulating coefficient a will preclude the natural scaling properties of pure fractional Laplace operators. In this respect, the aforementioned proof of the Hölder regularity for solutions to the p -fractional Laplace equation via the approach by Silvestre is applicable with no substantial modifications to the inhomogeneous case with a bounded datum f ; see Remark 4.3 in [36] and Lemma 1 in [26]. On the contrary, the nonlocal double phase equations treated here will require further efforts. Precisely, in order to carefully accommodate the presence of the datum f , we need to take into account an appropriate analysis of the scaling effects on the double phase equations, which will influence the involved kernels and the modulating coefficient as well. We refer in particular to the detailed computations about such a nontrivial extension in the forthcoming proofs of Proposition 2 and Lemma 1; see also the appendix. Finally, the wide range of integrability we are considering here will force us to work in three different ranges depending on the interaction between the exponents $q \geq p$, which can vary from singular to degenerate cases.

Several questions naturally arise:

- Firstly, it is worth remarking that the result presented here does apply to bounded solutions. It could be interesting to treat unbounded solutions, namely by truncation and dealing with the resulting error term as a right hand-side, in the same flavour of the papers [15, 16], where the local boundedness for p -fractional minimizers is proven, given that a precise quantity, the so-called “nonlocal tail”, can be controlled; see in particular the local vs. nonlocal interpolation estimate in [16, Theorem 1.1]. Notice that the approach in the aforementioned papers – as well as in the local counterpart of the double phase operators [11, 12] – is in the spirit of De Giorgi-Nash-Moser, being addressed to energy minimizers/weak solutions, whereas the approach presented here is more in the spirit of Krylov-Safonov.

- For this, a second natural question is whether or not, and under which assumptions on the structural quantities, the viscosity solutions to nonlocal double phase equations are indeed fractional harmonic functions and/or weak solutions, and vice versa. In this respect, let us observe that one cannot plainly applied the results for p -fractional minimizers as obtained in the recent paper [23] together with those in the forthcoming paper [21], whose proofs seem to be feasible only for a restrict class of kernels which cannot include a general modulating coefficient.

- Third, in the same spirit of the series of paper by Baroni, Colombo, and Mingione, one would expect higher differentiability and regularity results for the bounded solutions to nonlocal double phase equations. We refer to [3] and in particular to the paper [12], where it has been established the local gradient Hölder continuity of minima provided a sharp balancing condition between the closeness of p and q and the regularity of $a(\cdot)$ is satisfied. For what concerns the nonlocal case, it could be useful to start from the estimates obtained in the present paper, together with those in the very relevant results obtained for the fractional p -Laplace equation by Brasco, Lindgren, and Schikorra [5, 6].

- Also, again in clear accordance with the local counterpart [12, Theorem 1.2], one would expect self-improving properties of the solutions to (1.4). For this, one should extend the recent nonlocal Gehring-type theorems proven in [24, 35].

- Finally, both in the local and in the nonlocal double phase theory, nothing is known about the regularity for solutions to parabolic double phase equations.

To summarize. The regularity result in the present paper seems to be the very first one for nonlocal double phase equations; i. e., a wide class of equations led by fractional operators exhibiting non-standard growth conditions and non-uniform ellipticity properties, the latter according to the geometry of the level set of a modulating coefficient $a(\cdot, \cdot)$. Precisely, we prove Hölder continuity for bounded viscosity solutions, by extending to the fractional framework a recent sharp result by Colombo and Mingione, with the substantial difference on the requirement of the modulating coefficient $a(\cdot, \cdot)$, which is here assumed to belong only to L^∞ . We believe our estimates to be important in a forthcoming nonlocal theory of double phase operators.

2. SETTING OF THE PROBLEM AND DESCRIPTION OF THE MAIN RESULT

In this section we set the problem we are dealing with, and we state our main result, by adding further considerations about the involved quantities and assumptions.

Consider the following inhomogeneous nonlocal double phase equation,

$$(2.1) \quad \mathcal{L}u = f,$$

where f is bounded and the integro-differential operator \mathcal{L} is given by

$$(2.2) \quad \begin{aligned} \mathcal{L}u(x) &:= P.V. \int_{\mathbb{R}^n} |u(x) - u(x+y)|^{p-2} (u(x) - u(x+y)) K_{sp}(x, y) dy \\ &+ P.V. \int_{\mathbb{R}^n} a(x, y) |u(x) - u(x+y)|^{q-2} (u(x) - u(x+y)) K_{tq}(x, y) dy. \end{aligned}$$

In the display above, the symbol $P.V.$ stands for ‘‘principal value’’; in the rest of the paper, when not important, or clear from the context, we shall omit such a symbol. The measurable kernels K_{sp} and K_{tq} essentially behave like (s, p) and (t, q) -kernels, respectively; see [17, 31] for the basics on fractional Sobolev spaces. More precisely, there exists a positive constant Λ such that

$$(2.3) \quad \begin{cases} \Lambda^{-1}|y|^{-n-sp} \leq K_{sp}(x, y) \leq \Lambda|y|^{-n-sp}, \\ K_{sp}(x, y) = K_{sp}(x, -y), \end{cases} \quad \text{and} \quad \begin{cases} \Lambda^{-1}|y|^{-n-tq} \leq K_{tq}(x, y) \leq \Lambda|y|^{-n-tq}, \\ K_{tq}(x, y) = K_{tq}(x, -y). \end{cases}$$

The differentiability orders $s, t \in (0, 1)$ and the summability exponents $p, q > 1$ are required such that

$$(2.4) \quad p > \frac{1}{1-s} \quad \text{if } p < 2, \quad q > \frac{1}{1-t},$$

and

$$(2.5) \quad 1 \leq \frac{q}{p} \leq \min \left\{ \frac{s}{t}, 1+s \right\};$$

for motivations about the two requirements above we refer to Remarks 1–3 below. Finally, the modulating coefficient $a = a(\cdot, \cdot)$ is assumed to be measurable and such that

$$(2.6) \quad 0 \leq a(x, y) \leq M \quad \text{for a.e. } (x, y) \in \mathbb{R}^n \times \mathbb{R}^n.$$

In order to prove that viscosity solutions u could behave as classical solutions (see in particular forthcoming Proposition 1), we will naturally require that the corresponding nonlocal double phase energy of u is finite; i.e.,

$$(2.7) \quad \int_{\mathbb{R}^n} \int_{\mathbb{R}^n} \frac{|u(x) - u(x+y)|^p}{|y|^{n+sp}} + a(x, y) \frac{|u(x) - u(x+y)|^q}{|y|^{n+tq}} dx dy < \infty.$$

Our main result is that bounded viscosity solutions to (2.1) with f bounded are locally Hölder continuous, as stated in Theorem 1 below. For the natural definition of viscosity solutions to nonlocal double phase equations, we refer to forthcoming Section 3.

Theorem 1. *Let the nonlocal double phase operator \mathcal{L} be defined in (2.2), under the assumptions (2.3)–(2.7), and let f be in $L^\infty(B_2)$. If u is a bounded viscosity solution to*

$$\mathcal{L}u = f \quad \text{in } B_2,$$

then $u \in C^{0,\gamma}(B_1)$ for some $\gamma = \gamma(\mathbf{data}) \in (0, 1)$.

In order to shorten the notation, in the statement above as well as in the rest of the paper, we use the symbol \mathbf{data} to express the natural dependency of the constants as follows

$$\mathbf{data} := n, p, q, s, t, M, \Lambda, \|u\|_{L^\infty(\mathbb{R}^n)}, \|f\|_{L^\infty(B_2)}.$$

Remark 1. As mentioned in the introduction, in the local case, the sharp $C^{1,\beta}$ -regularity result by Colombo and Mingione is strictly related to the effect of the Lavrentiev phenomenon, which can be avoided in the “a priori bounded” case by assuming $1 \leq q/p \leq 1 + \alpha/p$, α being the Hölder exponent of $a(\cdot)$. In clear accordance, the range of validity of our result in (2.5) is precisely given by $1 \leq q/p \leq \min\{s/t, 1 + s\}$, being informally $\alpha = 0$ here. Notice also that such a bound can be improved when considering homogeneous equations; i. e., when $f \equiv 0$, as follows, $1 \leq q/p \leq s/t$. As we will see in the following, this is strictly related to the scaling properties of the nonlocal double phase equations.

Remark 2. Condition (2.4)₂ is due to the presence of the modulating coefficient $a(\cdot, \cdot)$ which, in view of (2.6), is only bounded. In fact, concerning the integrability exponent p , we notice that the assumption in (2.4)₁ applies only when $p < 2$, while, if no extra regularity is given on $a(\cdot, \cdot)$, the assumption in (2.4)₂ becomes necessary in order to deal with the q -part of the involved energy functional. On the other hand, if a belongs to $C^{0,\alpha}(\mathbb{R}^n)$ for some $\alpha \in (0, 1]$, condition (2.4)₂ can be improved as follows

$$\begin{cases} q > \frac{1-\alpha}{1-t} & \text{if } q \geq 2, \\ q > \frac{1}{1-t} & \text{if } q < 2; \end{cases}$$

see Lemma 6 in the appendix. This is consistent with the more complex structure of nonlocal double phase equations with respect to that of pure $p/p(x)$ -fractional equations.

Remark 3. It is worth noticing that the estimates obtained in the present paper are not uniform with respect to the differentiability exponents s and t as they approach 1. This is consistent with the result in the local case. Otherwise, Theorem 1 would have implied a very general Hölder continuity result for solutions to the local double phase problem without requiring the Hölder continuity of the modulating coefficient $a(\cdot, \cdot)$, in contrast with the sharpness of the results in [11, 12]. For Hölder estimates and some higher regularity result for related (s, p) -Laplace equations when s approach 1, we refer to [4].

3. VISCOSITY SOLUTIONS TO NONLOCAL DOUBLE PHASE PROBLEMS

Let us provide the natural definition of nonlocal viscosity solutions to (4.2), by also showing their connection with the classical solutions. We have the following

Definition 1. *Let $\Omega \subset \mathbb{R}^n$ be an open subset and \mathcal{L} be as in (4.1), under assumptions (2.3)-(2.6). An upper semicontinuous function $u \in L_{\text{loc}}^\infty(\Omega)$ is a subsolution of $\mathcal{L}(\cdot) = C$ in Ω , and we write*

“ u is such that $\mathcal{L}(u) \leq C$ in Ω in the viscosity sense,,

if the following statement holds: whenever $x_0 \in \Omega$ and $\varphi \in C^2(B_\varrho(x_0))$ for some $\varrho > 0$ are so that

$$\varphi(x_0) = u(x_0), \quad \varphi(x) \geq u(x) \quad \text{for all } x \in B_\varrho(x_0) \Subset \Omega,$$

then we have $\mathcal{L}\varphi_\varrho(x_0) \leq C$, where

$$\varphi_\varrho := \begin{cases} \varphi & \text{in } B_\varrho(x_0) \\ u & \text{in } \mathbb{R}^n \setminus B_\varrho(x_0). \end{cases}$$

A viscosity supersolution is defined in an analogous fashion, and a viscosity solution is a function which is both a subsolution and a supersolution.

As customary, in the definition above, we denoted by $B_\rho = B_\rho(x_0)$ the ball of radius ρ centered in x_0 . We will keep this notation throughout the rest of the paper. In the proposition below, we show that as soon as we can touch a viscosity subsolution to (4.2) with a C^2 -function, then it behaves as a classical subsolution. The proof will extend to the double phase problems a by-now classical approach, as firstly seen in [9] for fully nonlinear integro-differential operators.

Proposition 1. *Under assumptions (2.3)-(2.7), suppose that $\mathcal{L}u \leq C$ in B_1 in the viscosity sense. If $\varphi \in C^2(B_\varrho(x_0))$ is such that*

$$\varphi(x_0) = u(x_0), \quad \varphi(x) \geq u(x) \quad \text{in } B_\varrho(x_0) \Subset B_1,$$

for some $0 < \varrho < 1$, then $\mathcal{L}u$ is defined in the pointwise sense at x_0 and $\mathcal{L}u(x_0) \leq C$.

Proof. For $0 < \varrho' \leq \varrho$, set

$$\varphi_{\varrho'} := \begin{cases} \varphi & \text{in } B_{\varrho'}(x_0) \\ u & \text{in } \mathbb{R}^n \setminus B_{\varrho'}(x_0). \end{cases}$$

Since u is a viscosity subsolution in the sense of Definition 1, then

$$(3.1) \quad \mathcal{L}\varphi_{\varrho'}(x_0) \leq C.$$

The proof will now follows that of the analogous result for the p -Laplace equation in [26], which extends to the nonlinear case the original proof by Caffarelli and Silvestre in [9, Lemma 3.3]. Clearly, we have to take into account the competition between the nonlocal kernels modulated by the coefficient $a(\cdot, \cdot)$, and this will require some

modifications. Firstly, by introducing a similar terminology to the one adopted in [26], we define the following quantities

$$\begin{aligned}\delta_p(\varphi_{\varrho'}, x, y) &:= \frac{1}{2}|\varphi_{\varrho'}(x) - \varphi_{\varrho'}(x+y)|^{p-2}(\varphi_{\varrho'}(x) - \varphi_{\varrho'}(x+y)) \\ &\quad + \frac{1}{2}|\varphi_{\varrho'}(x) - \varphi_{\varrho'}(x-y)|^{p-2}(\varphi_{\varrho'}(x) - \varphi_{\varrho'}(x-y)), \\ \delta_q(\varphi_{\varrho'}, x, y) &:= \frac{1}{2}|\varphi_{\varrho'}(x) - \varphi_{\varrho'}(x+y)|^{q-2}(\varphi_{\varrho'}(x) - \varphi_{\varrho'}(x+y))a(x, y) \\ &\quad + \frac{1}{2}|\varphi_{\varrho'}(x) - \varphi_{\varrho'}(x-y)|^{q-2}(\varphi_{\varrho'}(x) - \varphi_{\varrho'}(x-y))a(x, -y),\end{aligned}$$

and we consider the corresponding positive and negative part defined as follows,

$$\begin{aligned}\delta_p^\pm(\varphi_{\varrho'}, x, y) &:= \max \left\{ \pm \delta_p(\varphi_{\varrho'}, x, y), 0 \right\}, \\ \delta_q^\pm(\varphi_{\varrho'}, x, y) &:= \max \left\{ \pm \delta_q(\varphi_{\varrho'}, x, y), 0 \right\}.\end{aligned}$$

Since $\varphi \in C^2(B_\varrho(x_0))$, by keeping in mind the structural assumptions on the kernels, from (3.1) we can deduce that

$$\begin{aligned}C &\geq \mathcal{L}\varphi_{\varrho'}(x_0) \\ &= \int_{\mathbb{R}^n \setminus B_{\varrho'}(0)} |\varphi_{\varrho'}(x_0) - \varphi_{\varrho'}(x_0+y)|^{p-2}(\varphi_{\varrho'}(x_0) - \varphi_{\varrho'}(x_0+y))K_{sp}(x_0, y)dy \\ &\quad + \int_{\mathbb{R}^n \setminus B_{\varrho'}(0)} a(x_0, y)|\varphi_{\varrho'}(x_0) - \varphi_{\varrho'}(x_0+y)|^{q-2}(\varphi_{\varrho'}(x_0) - \varphi_{\varrho'}(x_0+y))K_{tq}(x_0, y)dy \\ &\quad + \lim_{\varepsilon \rightarrow 0^+} \int_{B_{\varrho'}(0) \setminus B_\varepsilon(0)} |\varphi_{\varrho'}(x_0) - \varphi_{\varrho'}(x_0+y)|^{p-2}(\varphi_{\varrho'}(x_0) - \varphi_{\varrho'}(x_0+y))K_{sp}(x_0, y)dy \\ &\quad + \lim_{\varepsilon \rightarrow 0^+} \int_{B_{\varrho'}(0) \setminus B_\varepsilon(0)} a(x_0, y)|\varphi_{\varrho'}(x_0) - \varphi_{\varrho'}(x_0+y)|^{q-2}(\varphi_{\varrho'}(x_0) - \varphi_{\varrho'}(x_0+y))K_{tq}(x_0, y)dy \\ &= \int_{\mathbb{R}^n \setminus B_{\varrho'}(0)} \left(\delta_p(\varphi_{\varrho'}, x_0, y)K_{sp}(x_0, y) + \delta_q(\varphi_{\varrho'}, x_0, y)K_{tq}(x_0, y) \right) dy \\ &\quad + \lim_{\varepsilon \rightarrow 0^+} \int_{B_{\varrho'}(0) \setminus B_\varepsilon(0)} \frac{1}{2}|\varphi(x_0) - \varphi(x_0+y)|^{p-2}(\varphi(x_0) - \varphi(x_0+y))K_{sp}(x_0, y)dy \\ &\quad + \lim_{\varepsilon \rightarrow 0^+} \int_{B_{\varrho'}(0) \setminus B_\varepsilon(0)} \frac{1}{2}|\varphi(x_0) - \varphi(x_0-y)|^{p-2}(\varphi(x_0) - \varphi(x_0-y))K_{sp}(x_0, -y)dy \\ &\quad + \lim_{\varepsilon \rightarrow 0^+} \int_{B_{\varrho'}(0) \setminus B_\varepsilon(0)} \frac{a(x_0, y)}{2}|\varphi(x_0) - \varphi(x_0+y)|^{q-2}(\varphi(x_0) - \varphi(x_0+y))K_{tq}(x_0, y)dy \\ &\quad + \lim_{\varepsilon \rightarrow 0^+} \int_{B_{\varrho'}(0) \setminus B_\varepsilon(0)} \frac{a(x_0, -y)}{2}|\varphi(x_0) - \varphi(x_0-y)|^{q-2}(\varphi(x_0) - \varphi(x_0-y))K_{tq}(x_0, -y)dy\end{aligned}$$

$$\begin{aligned}
&= \int_{\mathbb{R}^n \setminus B_{\varrho'}(0)} \left(\delta_p(\varphi_{\varrho'}, x_0, y) K_{sp}(x_0, y) + \delta_q(\varphi_{\varrho'}, x_0, y) K_{tq}(x_0, y) \right) dy \\
&\quad + \int_{B_{\varrho'}(0)} \left(\delta_p(\varphi, x_0, y) K_{sp}(x_0, y) + \delta_q(\varphi, x_0, y) K_{tq}(x_0, y) \right) dy \\
(3.2) \quad &= \int_{\mathbb{R}^n} \left(\delta_p(\varphi_{\varrho'}, x_0, y) K_{sp}(x_0, y) + \delta_q(\varphi_{\varrho'}, x_0, y) K_{tq}(x_0, y) \right) dy,
\end{aligned}$$

where, we first operated the change of variable $y \mapsto -y$, used (2.3) and then, by (2.4) and the fact that $\varphi_{\varrho'} \equiv \varphi$ in $B_{\varrho'}$, with $\varphi \in C^2(B_{\varrho'}(x_0))$, we noticed that the singular integrals appearing in the previous display actually converge.

Moreover, given that for $0 < \varsigma_1 < \varsigma_2 < \varrho$ one has $\varphi_{\varsigma_2} \geq \varphi_{\varsigma_1} \geq u$, we can recall the very definition of the δ 's, (2.3) and (2.6), to get

$$(3.3) \quad \delta_r(\varphi_{\varsigma_2}, x_0, y) \leq \delta_r(\varphi_{\varsigma_1}, x_0, y) \leq \delta_r(u, x_0, y),$$

with $r = \{p, q\}$ and $\varsigma_1 < \varsigma_2 < \varrho$. Therefore we deduce that

$$\begin{aligned}
(3.4) \quad \delta_p^-(u, x_0, y) + \delta_q^-(u, x_0, y) &\leq \delta_p^-(\varphi_{\varsigma}, x_0, y) + \delta_q^-(\varphi_{\varsigma}, x_0, y) \\
&\leq |\delta_p(\varphi_{\varrho}, x_0, y)| + |\delta_q(\varphi_{\varrho}, x_0, y)|,
\end{aligned}$$

for all $0 < \varsigma < \varrho$. Using (2.4), the content of Lemma 6 in the appendix and the fact that $\varphi \in C^2(B_{\varrho}(x_0))$, we have that

$$|\delta_p(\varphi_{\varrho}, x_0, \cdot)| K_{sp}(x_0, \cdot) + |\delta_q(\varphi_{\varrho}, x_0, \cdot)| K_{tq}(x_0, \cdot) \in L^1(\mathbb{R}^n),$$

and thus $\delta_p^-(u, x_0, \cdot) K_{sp}(x_0, \cdot) + \delta_q^-(u, x_0, \cdot) K_{tq}(x_0, \cdot)$ is integrable. Furthermore, we have

$$\begin{aligned}
&\int_{\mathbb{R}^n} \left(\delta_p^+(\varphi_{\varrho'}, x_0, y) K_{sp}(x_0, y) + \delta_q^+(\varphi_{\varrho'}, x_0, y) K_{tq}(x_0, y) \right) dy \\
&\quad = \int_{\mathbb{R}^n} \left(\delta_p^-(\varphi_{\varrho'}, x_0, y) K_{sp}(x_0, y) + \delta_p^-(\varphi_{\varrho'}, x_0, y) K_{sp}(x_0, y) \right. \\
&\quad \quad \left. + \delta_q(\varphi_{\varrho'}, x_0, y) K_{tq}(x_0, y) + \delta_q^-(\varphi_{\varrho'}, x_0, y) K_{tq}(x_0, y) \right) dy \\
(3.5) \quad &\stackrel{(3.2)}{\leq} \int_{\mathbb{R}^n} \left(\delta_p^-(\varphi_{\varrho'}, x_0, y) K_{sp}(x_0, y) + \delta_q^-(\varphi_{\varrho'}, x_0, y) K_{tq}(x_0, y) \right) dy + C.
\end{aligned}$$

Hence, for $\varsigma_1 < \varsigma_2$,

$$\begin{aligned}
&\int_{\mathbb{R}^n} \left(\delta_p^+(\varphi_{\varsigma_1}, x_0, y) K_{sp}(x_0, y) + \delta_q^+(\varphi_{\varsigma_1}, x_0, y) K_{tq}(x_0, y) \right) dy \\
&\quad \stackrel{(3.5)}{\leq} \int_{\mathbb{R}^n} \left(\delta_p^-(\varphi_{\varsigma_1}, x_0, y) K_{sp}(x_0, y) + \delta_q^-(\varphi_{\varsigma_1}, x_0, y) K_{tq}(x_0, y) \right) dy + C
\end{aligned}$$

$$(3.6) \quad \stackrel{(3.3)}{\leq} \int_{\mathbb{R}^n} \left(\delta_p^-(\varphi_{\varsigma_2}, x_0, y) K_{sp}(x_0, y) + \delta_q^-(\varphi_{\varsigma_2}, x_0, y) K_{tq}(x_0, y) \right) dy + C < \infty.$$

Since

$$(3.7) \quad \delta_p^+(\varphi_{\varrho'}, x_0, y) + \delta_q^+(\varphi_{\varrho'}, x_0, y) \rightarrow \delta_p^+(u, x_0, y) + \delta_q^+(u, x_0, y) \text{ as } \varrho' \rightarrow 0^+,$$

and $\delta_r^+(\varphi_{\varrho'}, x_0, y) = \delta_r(\varphi_{\varrho'}, x_0, y) + \delta_r^-(\varphi_{\varrho'}, x_0, y)$, from (3.3), (3.4), (3.7), the monotone convergence theorem and the dominated one, we have

$$\begin{aligned} & \int_{\mathbb{R}^n} \left(\delta_p^+(\varphi_{\varrho'}, x_0, y) K_{sp}(x_0, y) + \delta_q^+(\varphi_{\varrho'}, x_0, y) K_{tq}(x_0, y) \right) dy \\ & \qquad \qquad \qquad \downarrow \\ & \int_{\mathbb{R}^n} \left(\delta_p^+(u, x_0, y) K_{sp}(x_0, y) + \delta_q^+(u, x_0, y) K_{tq}(x_0, y) \right) dy, \end{aligned}$$

as ϱ' goes to 0^+ . Now, using in (3.6) the fact that $\varsigma \mapsto \delta_r^-(\varphi_\varsigma, x_0, y)$ is non decreasing, we obtain

$$(3.8) \quad \begin{aligned} & \int_{\mathbb{R}^n} \left(\delta_p^+(u, x_0, y) K_{sp}(x_0, y) + \delta_q^+(u, x_0, y) K_{tq}(x_0, y) \right) dy \\ & \leq \int_{\mathbb{R}^n} \left(\delta_p^-(\varphi_{\varrho'}, x_0, y) K_{sp}(x_0, y) + \delta_q^-(\varphi_{\varrho'}, x_0, y) K_{tq}(x_0, y) \right) dy + C < \infty, \end{aligned}$$

for all $0 < \varrho' < \varrho$. This allows us to conclude that $\delta_p^+(u, x_0, \cdot) K_{sp}(\cdot) + \delta_q^+(u, x_0, \cdot) K_{tq}(\cdot)$ is integrable. So that, by (3.4) and the monotone convergence theorem, we can pass to the limit as $\varrho' \rightarrow 0^+$ in the right-hand side of (3.8). We get

$$\begin{aligned} & \int_{\mathbb{R}^n} \left(\delta_p^+(u, x_0, y) K_{sp}(x_0, y) + \delta_q^+(u, x_0, y) K_{tq}(x_0, y) \right) dy \\ & \leq \int_{\mathbb{R}^n} \left(\delta_p^-(u, x_0, y) K_{sp}(x_0, y) + \delta_q^-(u, x_0, y) K_{tq}(x_0, y) \right) dy + C, \end{aligned}$$

which means

$$\int_{\mathbb{R}^n} \delta_p(u, x_0, y) K_{sp}(x_0, y) + \delta_q(u, x_0, y) K_{tq}(x_0, y) dy \leq C.$$

Finally, by applying $-y \mapsto y$ in the display above, we end up with

$$\begin{aligned} & \int_{\mathbb{R}^n} |u(x_0) - u(x_0 + y)|^{p-2} (u(x_0) - u(x_0 + y)) K_{sp}(x_0, y) dy \\ & + \int_{\mathbb{R}^n} a(x_0, y) |u(x_0) - u(x_0 + y)|^{q-2} (u(x_0) - u(x_0 + y)) K_{tq}(x_0, y) dy \leq C; \end{aligned}$$

i. e., $\mathcal{L}u(x_0)$ exists in the pointwise sense and $\mathcal{L}u(x_0) \leq C$, as desired. \square

4. FUNDAMENTAL REGULARITY ESTIMATES

In this section we set the background for the proof of Theorem 1, whose core is a refinement result for inhomogeneous nonlocal double phase equations given in forthcoming Lemma 1 which goes back to the pioneering work by De Giorgi. We refer the reader to the important paper [36] for first results in this direction for fractional operators, which – as mentioned in the introduction – will be the starting point of our main proof.

Let us denote by β any radial map which is C^2 -regular, vanishes outside B_1 , and it is non-increasing along rays from the origin. The precise expression of such function β is not relevant; for the sake of simplicity, one can just keep in mind the following choice (with a slight abuse of notation),

$$\beta(x) = \beta(|x|) := \left((1 - |x|^2)^+ \right)^2.$$

We now need to introduce a slightly modified version of the original operator in (2.2). Precisely, for a positive, absolute constant \hat{c} we shall consider

$$(4.1) \quad \begin{aligned} \hat{\mathcal{L}}u(x) &:= P.V. \int_{\mathbb{R}^n} |u(x) - u(x+y)|^{p-2} (u(x) - u(x+y)) K_{sp}(x, y) dy \\ &+ P.V. \int_{\mathbb{R}^n} \hat{c}a(x, y) |u(x) - u(x+y)|^{q-2} (u(x) - u(x+y)) K_{tq}(x, y) dy, \end{aligned}$$

with the corresponding problem

$$(4.2) \quad \hat{\mathcal{L}}u(x) := \hat{f} \text{ in } B_2,$$

for $\hat{f} \in L^\infty(B_2)$. Clearly, being the dilation constant \hat{c} strictly positive, all the assumptions (2.3)–(2.7) are satisfied, with the solely difference that the upper bound M appearing in (2.6) must be replaced by $\hat{M} := \hat{c}M$. Thus, in particular, the results in the previous section can be plainly applied to this family of nonlocal double phase operators.

We are ready to state and prove some precise inequalities. The statement in the proposition below could appear somewhat cumbersome, and this is so, as a natural consequence of the difficult non-uniformly growth of the involved operators as well as of their non-standard scaling and dilation properties (see also the appendix on Page 29). However, in order to achieve the proof of the fundamental result in Lemma 1, as well as for further developments in the nonlocal theory for the double phase equations, we need to keep these estimates as precise as follows.

Proposition 2. *Assume $p, q, s, t, a, K_{sp}, K_{tq}$ are as described in (2.3)–(2.6) and $\hat{c} > 0$ is an absolute constant. Then, for any $\varepsilon > 0$ there are $1/2 \geq \kappa > 0$ and $\eta > 0$ such that, if $q \geq p \geq 2$ and $q > 1/(1-t)$, there holds*

$$(4.3) \quad \begin{aligned} &2^{q-2} \kappa^{p-1} \int_{x+y \in B_1} |\beta(x) - \beta(x+y)|^{p-2} (\beta(x) - \beta(x+y)) K_{sp}(x, y) dy \\ &+ 2^{q-2} \kappa^{q-1} \int_{x+y \in B_1} \hat{c}a(x, y) |\beta(x) - \beta(x+y)|^{q-1} K_{tq}(x, y) dy \\ &+ 2^{q-2} \int_{x+y \notin B_1} |\kappa\beta(x) - \kappa\beta(x+y) + 2(|2(x+y)|^\eta - 1)|^{p-1} K_{sp}(x, y) dy \\ &+ 2^{q-2} \int_{x+y \notin B_1} \hat{c}a(x, y) \left| \kappa\beta(x) - \kappa\beta(x+y) + 2(|2(x+y)|^\eta - 1) \right|^{q-1} K_{tq}(x, y) dy \\ &+ (2 + \hat{c}M) 2^{q-1} \int_{y \notin B_{1/4}} \left((|8y|^\eta - 1)^{p-1} K_{sp}(x, y) + (|8y|^\eta - 1)^{q-1} K_{tq}(x, y) \right) dy \leq \frac{\varepsilon}{\Lambda 2^{n+sp+q}}, \end{aligned}$$

for all $x \in B_{3/4}$. If $q \geq 2$, $q > 1/(1-t)$ and $q \geq 2 \geq p > 1/(1-s)$, we have

$$\begin{aligned}
& (6^{q-1} + 2^{2q-3})\kappa^{p-1} \int_{x+y \in B_1} |\beta(x) - \beta(x+y)|^{p-1} K_{sp}(x, y) \, dy \\
& + 2^{q-2}\kappa^{q-1} \int_{x+y \in B_1} \hat{c}a(x, y) |\beta(x) - \beta(x+y)|^{q-1} K_{tq}(x, y) \, dy \\
& + (6^{q-1} + 2^{2q-3}) \int_{x+y \notin B_1} |\kappa\beta(x) - \kappa\beta(x+y) + 2(|2(x+y)|^\eta - 1)|^{p-1} K_{sp}(x, y) \, dy \\
& + 2^{q-2} \int_{x+y \notin B_1} \hat{c}a(x, y) \left| \kappa\beta(x) - \kappa\beta(x+y) + 2(|2(x+y)|^\eta - 1) \right|^{q-1} K_{tq}(x, y) \, dy \\
& + 2^{q-1}(2^{q-2} + \hat{c}M) \int_{y \notin B_{1/4}} \left((|8y|^\eta - 1)^{p-1} K_{sp}(y) + a(x, y)(|8y|^\eta - 1)^{q-1} K_{tq}(x, y) \right) \, dy \\
(4.4) \quad & \leq \frac{\varepsilon}{\Lambda 2^{n+sp+q}},
\end{aligned}$$

for any $x \in B_{3/4}$. Finally, if $2 > q > 1/(1-t)$ and $2 > p > 1/(1-s)$,

$$\begin{aligned}
& (3^{q-1} + 2^{q-1})\kappa^{p-1} \int_{x+y \in B_1} |\beta(x) - \beta(x+y)|^{p-1} K_{sp}(x, y) \, dy \\
& + (3^{q-1} + 2^{q-1})\kappa^{q-1} \int_{x+y \in B_1} \hat{c}a(x, y) |\beta(x) - \beta(x+y)|^{q-1} K_{tq}(x, y) \, dy \\
& + (3^{q-1} + 2^{q-1}) \int_{x+y \notin B_1} \left| \kappa\beta(x) - \kappa\beta(x+y) + 2(|2(x+y)|^\eta - 1) \right|^{p-1} K_{sp}(x, y) \, dy \\
& + (3^{q-1} + 2^{q-1}) \int_{x+y \notin B_1} \hat{c}a(x, y) \left| \kappa\beta(x) - \kappa\beta(x+y) + 2(|2(x+y)|^\eta - 1) \right|^{q-1} K_{tq}(x, y) \, dy \\
& + 2^{q-1}(1 + \hat{c}M) \int_{y \notin B_{1/4}} \left((|8y|^\eta - 1)^{p-1} K_{sp}(y) + \hat{c}a(x, y)(|8y|^\eta - 1)^{q-1} K_{tq}(x, y) \right) \, dy \\
(4.5) \quad & \leq \frac{\varepsilon}{\Lambda 2^{n+sp+q}},
\end{aligned}$$

again for all $x \in B_{3/4}$. Here κ and η depend on Λ , p , q , s , t , ε , M and \hat{c} .

Proof. For the ease of notation, let us define

$$\begin{aligned}
I_p & := 2^{q-2}\kappa^{p-1} \int_{x+y \in B_1} |\beta(x) - \beta(x+y)|^{p-2} (\beta(x) - \beta(x+y)) K_{sp}(x, y) \, dy, \\
I_q & := 2^{q-2}\kappa^{q-1} \int_{x+y \in B_1} \hat{c}a(x, y) |\beta(x) - \beta(x+y)|^{q-1} K_{tq}(x, y) \, dy, \\
II_p & := 2^{q-2} \int_{x+y \notin B_1} |\kappa\beta(x) - \kappa\beta(x+y) + 2(|2(x+y)|^\eta - 1)|^{p-1} K_{sp}(x, y) \, dy, \\
II_q & := 2^{q-2} \int_{x+y \notin B_1} \hat{c}a(x, y) \left| \kappa\beta(x) - \kappa\beta(x+y) + 2(|2(x+y)|^\eta - 1) \right|^{q-1} K_{tq}(x, y) \, dy, \\
III & := (2 + \hat{c}M) 2^{q-1} \int_{y \notin B_{1/4}} \left((|8y|^\eta - 1)^{p-1} K_{sp}(x, y) + (|8y|^\eta - 1)^{q-1} K_{tq}(x, y) \right) \, dy.
\end{aligned}$$

Case 1: $q \geq p \geq 2$ and $q > \frac{1}{1-t}$. The symmetry of the domain of integration and (2.3)

allow rewriting term I_p as

$$(4.6) \quad \begin{aligned} I_p &= 2^{q-3} \kappa^{p-1} \int_{x+y \in B_1} |\beta(x) - \beta(x+y)|^{p-2} (\beta(x) - \beta(x+y)) K_{sp}(x, y) \, dy \\ &+ 2^{q-3} \kappa^{p-1} \int_{x+y \in B_1} |\beta(x) - \beta(x-y)|^{p-2} (\beta(x) - \beta(x-y)) K_{sp}(x, y) \, dy. \end{aligned}$$

Since $\beta \in C^2(B_1)$, we easily see that

$$(4.7) \quad \|D\beta\|_{L^\infty} \leq 8 \quad \text{and} \quad \|D^2\beta\|_{L^\infty} \leq 16,$$

and, as in the proof of Lemma 6, we set

$$\begin{aligned} A &:= -(\beta(x) - \beta(x-y)), \\ B &:= (\beta(x) - \beta(x-y)) + (\beta(x) - \beta(x+y)). \end{aligned}$$

In these terms we can manipulate (4.6) and, from Lemma 2, (2.3), (2.4)₁ and (4.7)₂ we get

$$(4.8) \quad \begin{aligned} I_p &\leq 2^{q-3} \kappa^{p-1} \int_{x+y \in B_1} (|A+B|^{p-2}(A+B) - |A|^{p-2}A) K_{sp}(x, y) \, dy \\ &\leq (p-1) 2^{q-3} \kappa^{p-1} \int_{x+y \in B_1} |B|(|A|+|B|)^{p-2} \, dy \\ &\leq c \kappa^{p-1} \int_{x+y \in B_1} |y|^{p-n-sp} \, dy \leq c(n, p, q, s, \Lambda) \kappa^{p-1} \xrightarrow{\kappa \rightarrow 0^+} 0. \end{aligned}$$

Further, using this time (2.3), (2.4)₂, (2.6) and (4.7)₁ we estimate

$$(4.9) \quad |I_q| \leq c \kappa^{q-1} \int_{x+y \in B_1} |y|^{q-1-n-tq} \, dy \leq c(n, q, t, \Lambda, M, \hat{c}) \kappa^{q-1} \xrightarrow{\kappa \rightarrow 0^+} 0.$$

From estimates (4.8) and (4.9), we immediately obtain that $I_p + I_q \xrightarrow{\kappa \rightarrow 0^+} 0$.

Concerning the second couple of terms, we notice that, since conditions $x \in B_{3/4}$ and $x+y \notin B_1$ imply $y \notin B_{1/4}$ and therefore $|x| \leq 3|y|$, in view of (2.3) and the dominated convergence theorem, we can estimate as follows,

$$(4.10) \quad \begin{aligned} II_p &\leq c \kappa^{p-1} \int_{y \notin B_{1/4}} |y|^{-n-sp} \, dy + c \int_{y \notin B_{1/4}} (|8y|^\eta - 1)^{p-1} |y|^{-n-sp} \, dy \\ &\leq c \kappa^{p-1} + c \int_{y \notin B_{1/4}} (|8y|^\eta - 1)^{p-1} |y|^{-n-sp} \, dy \longrightarrow 0 \end{aligned}$$

as $\kappa \rightarrow 0^+$ and $\eta \rightarrow 0^+$ (notice also that the latter assures in particular $\eta < sp/(p-1)$), so that $|y|^{\eta(p-1)-n-sp}$ is integrable over $\mathbb{R}^n \setminus B_{1/4}$). Here $c = c(n, p, q, s, \Lambda)$. Analogously, we can estimate as above the following term,

$$(4.11) \quad \begin{aligned} II_q &\leq c \kappa^{q-1} \int_{y \notin B_{1/4}} |y|^{-n-tq} \, dy + c \int_{y \notin B_{1/4}} (|8y|^\eta - 1)^{q-1} |y|^{-n-tq} \, dy \\ &\leq c \kappa^{q-1} + c \int_{y \notin B_{1/4}} (|8y|^\eta - 1)^{q-1} |y|^{-n-tq} \, dy \longrightarrow 0, \end{aligned}$$

as $\kappa \rightarrow 0^+$ and $\eta \rightarrow 0^+$ (specifically, $\eta < tq/(q-1)$), for a non relabeled constant $c = c(n, p, q, t, M, \Lambda, \hat{c})$. Estimates (4.10)-(4.11) guarantee that $II_p + II_q \rightarrow 0$ as $\kappa, \eta \rightarrow 0^+$. Finally, remembering that η is supposed to go to zero, we can assume $\eta < \min \left\{ \frac{sp}{p-1}, \frac{tq}{q-1} \right\}$, thus it is easy to see that, by the dominated convergence theorem,

$$(4.12) \quad III \xrightarrow{\eta \rightarrow 0^+} 0.$$

Let us have a look to the term on the right-hand side of (4.3). By (2.3) and (2.6), for any $A_0 \subset B_2$ we have

$$\int_{A_0} \left(K_{sp}(x, y) + \hat{c}a(x, y)K_{tq}(x, y) \right) dy \geq \int_{A_0} \Lambda^{-1} |y|^{-n-sp} dy \geq \frac{|A_0|}{\Lambda 2^{n+sp}},$$

which yields

$$(4.13) \quad 2^{1-q} \inf_{A_0 \subset B_2, |A_0| > \varepsilon} \int_{A_0} \left(K_{sp}(x, y) + \hat{c}a(x, y)K_{tq}(x, y) \right) dy \geq \frac{\varepsilon}{\Lambda 2^{n+sp+q-1}},$$

so we can choose η_1, κ_1 sufficiently small in such a way that the sum $I_p + I_q + II_p + II_q + III$ can be controlled by the quantity in the right-hand side of (4.13), e. g., the number in (4.3).

Case 2: $q \geq 2 \geq p > 1/(1-s)$ and $q > \frac{1}{1-t}$. We only need to take care of the term in the first line of (4.4), since the other terms can be estimated as in the previous case: the fact that those are multiplied by a different constant will not affect the result. Let

$$IV := (6^{q-1} + 2^{2q-3})\kappa^{p-1} \int_{x, y \in B_1} |\beta(x) - \beta(x+y)|^{p-1} K_{sp}(x, y) dy,$$

We have, by Lagrange's Theorem, (4.7)₁, (2.4)₁ and (2.3), that

$$IV \leq c\kappa^{p-1} \int_{B_{7/4}} |y|^{p-1-n-sp} dy \xrightarrow{\kappa \rightarrow 0^+} 0,$$

with $c = c(n, p, q, \Lambda, s)$. Again, we can fix η_2 and κ_2 small enough so that (4.4) is satisfied.

Case 3: $2 \geq q > 1/(1-t)$ and $2 \geq p > 1/(1-s)$. In this case we will only consider the term in the second line of (4.5),

$$V := (3^{q-1} + 2^{q-1})\kappa^{q-1} \int_{x+y \in B_1} \hat{c}a(x, y) |\beta(x) - \beta(x+y)|^{q-1} K_{tq}(x, y) dy.$$

By Lagrange's Theorem, (4.7)₁, (2.6), (2.4)₂ and (2.3) we obtain

$$V \leq c \int_{B_{7/4}} |y|^{q-1-n-tq} dy \xrightarrow{\kappa \rightarrow 0^+} 0,$$

where $c = c(n, q, M, \Lambda, t, \hat{c})$. Hence, we can find η_3 and κ_3 for which (4.5) holds true, and this concludes the proof. \square

Remark 4. From now on, we will work with parameters $\eta := \min_{i=\{1,2,3\}} \eta_i > 0$ and $\kappa := \min_{i=\{1,2,3\}} \kappa_i > 0$, where the η_i 's, κ_i 's are those determined in Proposition 2. This choice is clearly motivated by the fact that these definitions assure that (4.3)–(4.5) are simultaneously matched.

Lemma 1. *Under assumptions (2.3)–(2.7), let η be as the one determined in Remark 4, and set*

$$(4.14) \quad \sigma := 2^{q-1} \int_{y \notin B_{1/4}} \left((|8y|^\eta - 1)^{p-1} |y|^{-n-sp} + (|8y|^\eta - 1)^{q-1} |y|^{-n-tq} \right) dy.$$

If u is such that $|B_1 \cap \{x: u(x) \leq 0\}| > \varepsilon$ and

$$(4.15) \quad \begin{cases} \hat{\mathcal{L}}u \leq \sigma & \text{in } B_1, \\ u \leq 1 & \text{in } B_1, \\ u(x) \leq 2|2x|^\eta - 1 & \text{in } \mathbb{R}^n \setminus B_1, \end{cases}$$

then there exists $\theta = \theta(n, p, q, s, t, M, \Lambda, \hat{c}) > 0$ such that

$$u \leq 1 - \theta \text{ in } B_{1/2}.$$

Proof. Let κ be as in Remark 4 and set $\theta := \kappa(\beta(1/2) - \beta(3/4)) = 95\kappa/256$. By contradiction, suppose that there is $x_0 \in B_{1/2}$ such that $u(x_0) > 1 - \theta$. Then $u(x_0) + \kappa\beta(1/2) > 1 + \kappa\beta(3/4)$. Moreover, since β is non increasing along rays, for any $y \in B_1 \setminus B_{3/4}$ there holds

$$u(x_0) + \kappa\beta(x_0) > u(x_0) + \kappa\beta(1/2) > 1 + \kappa\beta(3/4) \geq u(y) + \kappa\beta(y).$$

This shows that the maximum of $u + \kappa\beta$ in B_1 is attained in $B_{3/4}$ and it is strictly larger than one. Let $\bar{x} \in B_{3/4}$ be such a maximum point. We aim to estimate $\mathcal{L}(u + \kappa\beta)(\bar{x})$ from above and below as to reach a contradiction with (4.3)–(4.5). Notice that $-\kappa\beta + (u + \kappa\beta)(\bar{x})$ touches u from above at \bar{x} , thus, being $\beta \in C_c^2(B_1)$, by Proposition 1,

$$(4.16) \quad \hat{\mathcal{L}}u(\bar{x}) \leq \sigma \text{ in the pointwise sense.}$$

We begin by estimating $\hat{\mathcal{L}}(u + \kappa\beta)(\bar{x})$ from below. We then rewrite

$$\mathcal{L}(u + \kappa\beta)(\bar{x}) = \lim_{\varrho \rightarrow 0^+} I_\varrho + I_2,$$

where

$$\begin{aligned} I_\varrho := & \int_{\bar{x}+y \in B_1, y \notin B_\varrho} \left(|u(\bar{x}) + \kappa\beta(\bar{x}) - u(\bar{x}+y) - \kappa\beta(\bar{x}+y)|^{p-2} \right. \\ & \left. \times (u(\bar{x}) + \kappa\beta(\bar{x}) - u(\bar{x}+y) - \kappa\beta(\bar{x}+y)) K_{sp}(\bar{x}, y) \right) dy \\ & + \int_{\bar{x}+y \in B_1, y \notin B_\varrho} \left(\hat{c}a(\bar{x}, y) |u(\bar{x}) + \kappa\beta(\bar{x}) - u(\bar{x}+y) - \kappa\beta(\bar{x}+y)|^{q-2} \right. \\ & \left. \times (u(\bar{x}) + \kappa\beta(\bar{x}) - u(\bar{x}+y) - \kappa\beta(\bar{x}+y)) K_{tq}(\bar{x}, y) \right) dy, \end{aligned}$$

$$\begin{aligned}
I_2 &:= \int_{\bar{x}+y \notin B_1} \left(|u(\bar{x}) + \kappa\beta(\bar{x}) - u(\bar{x}+y) - \kappa\beta(\bar{x}+y)|^{p-2} \right. \\
&\quad \left. \times (u(\bar{x}) + \kappa\beta(\bar{x}) - u(\bar{x}+y) - \kappa\beta(\bar{x}+y)) K_{sp}(\bar{x}, y) \right) dy \\
&\quad + \int_{\bar{x}+y \notin B_1} \left(\hat{c}a(\bar{x}, y) |u(\bar{x}) + \kappa\beta(\bar{x}) - u(\bar{x}+y) - \kappa\beta(\bar{x}+y)|^{q-2} \right. \\
&\quad \left. \times (u(\bar{x}) + \kappa\beta(\bar{x}) - u(\bar{x}+y) - \kappa\beta(\bar{x}+y)) K_{tq}(\bar{x}, y) \right) dy.
\end{aligned}$$

Set $A_0 := \{\bar{x} + y \in B_1 : u(\bar{x} + y) \leq 0\}$; by using that $u(\bar{x}) + \kappa\beta(\bar{x}) > 1$ is the maximum of $u + \kappa\beta$ in B_1 , we see that the integrand in I_ϱ is nonnegative and we have the following estimate

$$I_\varrho \geq \int_{A_0 \cap B_\varrho^c} \left((1 - \kappa\beta(\bar{x} + y))^{p-1} K_{sp}(\bar{x}, y) + \hat{c}a(\bar{x}, y) (1 - \kappa\beta(\bar{x} + y))^{q-1} K_{tq}(\bar{x}, y) \right) dy,$$

Since $\beta \leq 1$ and $\kappa \leq 1/2$, recalling also that $\hat{c} > 0$ and, by (2.6), $a(\cdot, \cdot)$ is nonnegative, we can deduce

$$\begin{aligned}
\liminf_{\varrho \rightarrow 0} I_\varrho &\geq 2^{1-q} \inf_{A \subset B_2, |A| > \varepsilon} \int_A \left(K_{sp}(\bar{x}, y) + \hat{c}a(\bar{x}, y) K_{tq}(\bar{x}, y) \right) dy \\
&\geq 2^{1-q} \inf_{A \subset B_2, |A| > \varepsilon} \int_A K_{sp}(\bar{x}, y) dy \geq \frac{\varepsilon}{\Lambda 2^{n+sp+q-1}}.
\end{aligned}$$

Let us take care of I_2 . Exploiting that $u(\bar{x}) + \kappa\beta(\bar{x}) > 1$, (4.15)₃ and that $\beta \equiv 0$ in $\mathbb{R}^n \setminus B_1$, we have

$$\begin{aligned}
I_2 &\geq \int_{\bar{x}+y \notin B_1} 2^{p-1} \left| 1 - |2(\bar{x} + y)|^\eta \right|^{p-2} \left(1 - |2(\bar{x} + y)|^\eta \right) K_{sp}(\bar{x}, y) dy \\
&\quad + \int_{\bar{x}+y \notin B_1} 2^{q-1} \hat{c}a(\bar{x}, y) \left| 1 - |2(\bar{x} + y)|^\eta \right|^{q-2} \left(1 - |2(\bar{x} + y)|^\eta \right) K_{tq}(\bar{x}, y) dy \\
&\geq \int_{y \notin B_{1/4}} 2^{p-1} \left| 1 - \left| 2 \left(\frac{3}{4} + |y| \right) \right|^\eta \right|^{p-2} \left(1 - \left| 2 \left(\frac{3}{4} + |y| \right) \right|^\eta \right) K_{sp}(\bar{x}, y) dy \\
&\quad + \int_{y \notin B_{1/4}} 2^{q-1} \hat{c}a(\bar{x}, y) \left| 1 - \left| 2 \left(\frac{3}{4} + |y| \right) \right|^\eta \right|^{q-2} \left(1 - \left| 2 \left(\frac{3}{4} + |y| \right) \right|^\eta \right) K_{tq}(\bar{x}, y) dy \\
&\geq -2^{q-1} \int_{y \notin B_{1/4}} \left((|8y|^\eta - 1)^{p-1} K_{sp}(\bar{x}, y) + \hat{c}a(\bar{x}, y) (|8y|^\eta - 1)^{q-1} K_{tq}(\bar{x}, y) \right) dy.
\end{aligned}$$

Adding together the content of the two displays above, we obtain

$$\begin{aligned}
\mathcal{L}(u + \kappa\beta)(\bar{x}) &\geq \frac{\varepsilon}{\Lambda 2^{n+sp+q-1}} \\
(4.17) \quad &- 2^{q-1} \int_{y \notin B_{1/4}} \left((|8y|^\eta - 1)^{p-1} K_{sp}(\bar{x}, y) + \hat{c}a(\bar{x}, y) (|8y|^\eta - 1)^{q-1} K_{tq}(\bar{x}, y) \right) dy.
\end{aligned}$$

Now, we want to estimate $\mathcal{L}(u + \kappa\beta)(\bar{x})$ from above, and for this we need to distinguish the following three cases: $q \geq p \geq 2$, $q \geq 2 \geq p$, and $2 \geq q \geq p$.

Case 1: $q \geq p \geq 2$ and $q > 1/(1-t)$. We split the integral into two parts:

$$\mathcal{L}(u + \kappa\beta)(\bar{x}) = I_1 + I_2,$$

where

$$\begin{aligned} I_1 &:= \int_{\bar{x}+y \in B_1} \left(|u(\bar{x}) + \kappa\beta(\bar{x}) - u(\bar{x}+y) - \kappa\beta(\bar{x}+y)|^{p-2} \right. \\ &\quad \left. \times (u(\bar{x}) + \kappa\beta(\bar{x}) - u(\bar{x}+y) - \kappa\beta(\bar{x}+y)) K_{sp}(\bar{x}, y) \right) dy \\ &\quad + \int_{\bar{x}+y \in B_1} \left(\hat{c}a(\bar{x}, y) |u(\bar{x}) + \kappa\beta(\bar{x}) - u(\bar{x}+y) - \kappa\beta(\bar{x}+y)|^{q-2} \right. \\ &\quad \left. \times (u(\bar{x}) + \kappa\beta(\bar{x}) - u(\bar{x}+y) - \kappa\beta(\bar{x}+y)) K_{tq}(\bar{x}, y) \right) dy, \\ I_2 &:= \int_{\bar{x}+y \notin B_1} \left(|u(\bar{x}) + \kappa\beta(\bar{x}) - u(\bar{x}+y) - \kappa\beta(\bar{x}+y)|^{p-2} \right. \\ &\quad \left. \times (u(\bar{x}) + \kappa\beta(\bar{x}) - u(\bar{x}+y) - \kappa\beta(\bar{x}+y)) K_{sp}(\bar{x}, y) \right) dy \\ &\quad + \int_{\bar{x}+y \notin B_1} \left(\hat{c}a(\bar{x}, y) |u(\bar{x}) + \kappa\beta(\bar{x}) - u(\bar{x}+y) - \kappa\beta(\bar{x}+y)|^{q-2} \right. \\ &\quad \left. \times (u(\bar{x}) + \kappa\beta(\bar{x}) - u(\bar{x}+y) - \kappa\beta(\bar{x}+y)) K_{tq}(\bar{x}, y) \right) dy, \end{aligned}$$

We start from I_1 by noticing that when $\bar{x} + y \in B_1$,

$$(4.18) \quad u(\bar{x}) + \kappa\beta(\bar{x}) - u(\bar{x}+y) - \kappa\beta(\bar{x}+y) \geq 0,$$

given that $u + \kappa\beta$ attains its maximum in B_1 in \bar{x} . So we can apply Lemma 3 to get

$$\begin{aligned} &|u(\bar{x}) + \kappa\beta(\bar{x}) - u(\bar{x}+y) - \kappa\beta(\bar{x}+y)|^{r-2} (u(\bar{x}) + \kappa\beta(\bar{x}) - u(\bar{x}+y) - \kappa\beta(\bar{x}+y)) \\ &\leq 2^{q-2} \left(|u(\bar{x}) - u(\bar{x}+y)|^{r-2} (u(\bar{x}) - u(\bar{x}+y)) + |\kappa\beta(\bar{x}) - \kappa\beta(\bar{x}+y)|^{r-2} \right. \\ &\quad \left. \times (\kappa\beta(\bar{x}) - \kappa\beta(\bar{x}+y)) \right), \end{aligned}$$

for $r \in \{p, q\}$. Hence, recalling also (2.6) and the fact that $\hat{c} > 0$,

$$\begin{aligned} I_1 &\leq 2^{q-2} \int_{\bar{x}+y \in B_1} |u(\bar{x}) - u(\bar{x}+y)|^{p-2} (u(\bar{x}) - u(\bar{x}+y)) K_{sp}(\bar{x}, y) dy \\ &\quad + 2^{q-2} \kappa^{p-1} \int_{\bar{x}+y \in B_1} |\beta(\bar{x}) - \beta(\bar{x}+y)|^{p-2} (\beta(\bar{x}) - \beta(\bar{x}+y)) K_{sp}(\bar{x}, y) dy \\ &\quad + 2^{q-2} \int_{\bar{x}+y \in B_1} \hat{c}a(\bar{x}, y) |u(\bar{x}) - u(\bar{x}+y)|^{q-2} (u(\bar{x}) - u(\bar{x}+y)) K_{tq}(\bar{x}, y) dy \\ &\quad + 2^{q-2} \kappa^{q-1} \int_{\bar{x}+y \in B_1} \hat{c}a(\bar{x}, y) |\beta(\bar{x}) - \beta(\bar{x}+y)|^{q-2} (\beta(\bar{x}) - \beta(\bar{x}+y)) K_{tq}(\bar{x}, y) dy. \end{aligned}$$

Now let us consider I_2 . Here it is not possible to apply directly Lemma 3, but from the assumptions we still have

$$u(\bar{x}) + \kappa\beta(\bar{x}) > 1 \quad \text{and} \quad u(\bar{x}+y) + \kappa\beta(\bar{x}+y) \leq 2|2(\bar{x}+y)|^\eta - 1,$$

which means that

$$u(\bar{x}) - u(\bar{x} + y) + \kappa\beta(\bar{x}) - \kappa\beta(\bar{x} + y) > 2(1 - |2(\bar{x} + y)|^\eta).$$

Adding $2(|2(\bar{x} + y)|^\eta - 1) > 0$ to both sides of the preceding inequality we increase the integrand and we make it nonnegative:

$$(4.19) \quad u(\bar{x}) - u(\bar{x} + y) + \kappa\beta(\bar{x}) - \kappa\beta(\bar{x} + y) + 2(|2(\bar{x} + y)|^\eta - 1) \geq 0$$

so, again, we can use Lemma 3. We obtain

$$\begin{aligned} I_2 &\leq \int_{\bar{x}+y \notin B_1} \left(|u(\bar{x}) - u(\bar{x} + y) + \kappa\beta(\bar{x}) - \kappa\beta(\bar{x} + y) + 2(|2(\bar{x} + y)|^\eta - 1)|^{p-2} \right. \\ &\quad \left. \times (u(\bar{x}) - u(\bar{x} + y) + \kappa\beta(\bar{x}) - \kappa\beta(\bar{x} + y) + 2(|2(\bar{x} + y)|^\eta - 1)) K_{sp}(\bar{x}, y) \right) dy \\ &\quad + \int_{\bar{x}+y \notin B_1} \left(\hat{c}a(\bar{x}, y) |u(\bar{x}) - u(\bar{x} + y) + \kappa\beta(\bar{x}) - \kappa\beta(\bar{x} + y) + 2(|2(\bar{x} + y)|^\eta - 1)|^{q-2} \right. \\ &\quad \left. \times (u(\bar{x}) - u(\bar{x} + y) + \kappa\beta(\bar{x}) - \kappa\beta(\bar{x} + y) + 2(|2(\bar{x} + y)|^\eta - 1)) K_{tq}(\bar{x}, y) \right) dy \\ &\leq 2^{q-2} \int_{\bar{x}+y \notin B_1} |u(\bar{x}) - u(\bar{x} + y)|^{p-2} (u(\bar{x}) - u(\bar{x} + y)) K_{sp}(\bar{x}, y) dy \\ &\quad + 2^{q-2} \int_{\bar{x}+y \notin B_1} \hat{c}a(\bar{x}, y) |u(\bar{x}) - u(\bar{x} + y)|^{q-2} (u(\bar{x}) - u(\bar{x} + y)) K_{tq}(\bar{x}, y) dy \\ &\quad + 2^{q-2} \int_{\bar{x}+y \notin B_1} \left(|\kappa\beta(\bar{x}) - \kappa\beta(\bar{x} + y) + 2(|2(\bar{x} + y)|^\eta - 1)|^{p-2} \right. \\ &\quad \left. \times (\kappa\beta(\bar{x}) - \kappa\beta(\bar{x} + y) + 2(|2(\bar{x} + y)|^\eta - 1)) K_{sp}(\bar{x}, y) \right) dy \\ &\quad + 2^{q-2} \int_{\bar{x}+y \notin B_1} \left(\hat{c}a(\bar{x}, y) |\kappa\beta(\bar{x}) - \kappa\beta(\bar{x} + y) + 2(|2(\bar{x} + y)|^\eta - 1)|^{q-2} \right. \\ &\quad \left. \times (\kappa\beta(\bar{x}) - \kappa\beta(\bar{x} + y) + 2(|2(\bar{x} + y)|^\eta - 1)) K_{tq}(\bar{x}, y) \right) dy. \end{aligned}$$

Adding the estimates for terms I_1 and I_2 and recalling (4.16), we end up with

$$\begin{aligned} &\mathcal{L}(u + \kappa\beta)(\bar{x}) \\ &\leq \mathcal{L}u(\bar{x}) + 2^{q-2} \kappa^{p-1} \int_{\bar{x}+y \in B_1} |\beta(\bar{x}) - \beta(\bar{x} + y)|^{p-2} (\beta(\bar{x}) - \beta(\bar{x} + y)) K_{sp}(\bar{x}, y) dy \\ &\quad + 2^{q-2} \kappa^{q-1} \int_{\bar{x}+y \in B_1} \hat{c}a(\bar{x}, y) |\beta(\bar{x}) - \beta(\bar{x} + y)|^{q-2} (\beta(\bar{x}) - \beta(\bar{x} + y)) K_{tq}(\bar{x}, y) dy \\ &\quad + 2^{q-2} \int_{\bar{x}+y \notin B_1} |\kappa\beta(\bar{x}) - \kappa\beta(\bar{x} + y) + 2(|2(\bar{x} + y)|^\eta - 1)|^{p-2} \\ &\quad + 2^{q-2} \int_{\bar{x}+y \notin B_1} \hat{c}a(\bar{x}, y) |\kappa\beta(\bar{x}) - \kappa\beta(\bar{x} + y) + 2(|2(\bar{x} + y)|^\eta - 1)|^{q-2} \\ &\quad \quad \times (\kappa\beta(\bar{x}) - \kappa\beta(\bar{x} + y) + 2(|2(\bar{x} + y)|^\eta - 1)) K_{tq}(\bar{x}, y) dy \end{aligned}$$

$$\begin{aligned}
&\leq \sigma + 2^{q-2}\kappa^{p-1} \int_{\bar{x}+y \in B_1} |\beta(\bar{x}) - \beta(\bar{x} + y)|^{p-1} K_{sp}(\bar{x}, y) \, dy \\
&\quad + 2^{q-2}\kappa^{q-1} \int_{\bar{x}+y \in B_1} \hat{c}a(\bar{x}, y) |\beta(\bar{x}) - \beta(\bar{x} + y)|^{q-1} K_{tq}(\bar{x}, y) \, dy \\
&\quad + 2^{q-2} \int_{\bar{x}+y \notin B_1} \left| \kappa\beta(\bar{x}) - \kappa\beta(\bar{x} + y) + 2 \left(|2(\bar{x} + y)|^\eta - 1 \right) \right|^{p-1} K_{sp}(\bar{x}, y) \, dy \\
(4.20) \quad &\quad + 2^{q-2} \int_{\bar{x}+y \notin B_1} \hat{c}a(\bar{x}, y) \left| \kappa\beta(\bar{x}) - \kappa\beta(\bar{x} + y) + 2 \left(|2(\bar{x} + y)|^\eta - 1 \right) \right|^{q-1} K_{tq}(\bar{x}, y) \, dy,
\end{aligned}$$

where we also used (4.15)₁. Coupling (4.17) and (4.20), together with the definition of σ , and also recalling (4.12), we conclude that

$$\begin{aligned}
\frac{\varepsilon}{\Lambda 2^{n+sp+q-1}} &\leq (2 + \hat{c}M) 2^{q-1} \int_{y \notin B_{1/4}} \left((|8y|^\eta - 1)^{p-1} K_{sp}(\bar{x}, y) + (|8y|^\eta - 1)^{q-1} K_{tq}(\bar{x}, y) \right) \, dy \\
&\quad + 2^{q-2}\kappa^{p-1} \int_{\bar{x}+y \in B_1} |\beta(\bar{x}) - \beta(\bar{x} + y)|^{p-2} (\beta(\bar{x}) - \beta(\bar{x} + y)) K_{sp}(\bar{x}, y) \, dy \\
&\quad + 2^{q-2}\kappa^{q-1} \int_{\bar{x}+y \in B_1} \hat{c}a(\bar{x}, y) |\beta(\bar{x}) - \beta(\bar{x} + y)|^{q-1} K_{tq}(\bar{x}, y) \, dy \\
&\quad + 2^{q-2} \int_{\bar{x}+y \notin B_1} \left| \kappa\beta(\bar{x}) - \kappa\beta(\bar{x} + y) + 2 \left(|2(\bar{x} + y)|^\eta - 1 \right) \right|^{p-1} K_{sp}(\bar{x}, y) \, dy \\
&\quad + 2^{q-2} \int_{\bar{x}+y \notin B_1} \hat{c}a(\bar{x}, y) \left| \kappa\beta(\bar{x}) - \kappa\beta(\bar{x} + y) + 2 \left(|2(\bar{x} + y)|^\eta - 1 \right) \right|^{q-1} K_{tq}(\bar{x}, y) \, dy \\
&\stackrel{(4.3)}{\leq} \frac{\varepsilon}{\Lambda 2^{n+sp+q}},
\end{aligned}$$

which is clearly a contradiction.

Case 2: $q \geq 2 \geq p > 1/(1-s)$ and $q > 1/(1-t)$. We look again at terms I_1, I_2 and we split them as

$$I_1 = I_1^p + I_1^q \quad \text{and} \quad I_2 = I_2^p + I_2^q,$$

where

$$\begin{aligned}
I_1^p &:= \int_{\bar{x}+y \in B_1} |u(\bar{x}) + \kappa\beta(\bar{x}) - u(\bar{x} + y) - \kappa\beta(\bar{x} + y)|^{p-2} \\
&\quad \times (u(\bar{x}) + \kappa\beta(\bar{x}) - u(\bar{x} + y) - \kappa\beta(\bar{x} + y)) K_{sp}(\bar{x}, y) \, dy, \\
I_1^q &:= \int_{\bar{x}+y \in B_1} \hat{c}a(\bar{x}, y) |u(\bar{x}) + \kappa\beta(\bar{x}) - u(\bar{x} + y) - \kappa\beta(\bar{x} + y)|^{q-2} \\
&\quad \times (u(\bar{x}) + \kappa\beta(\bar{x}) - u(\bar{x} + y) - \kappa\beta(\bar{x} + y)) K_{tq}(\bar{x}, y) \, dy, \\
I_2^p &:= \int_{\bar{x}+y \notin B_1} |u(\bar{x}) + \kappa\beta(\bar{x}) - u(\bar{x} + y) - \kappa\beta(\bar{x} + y)|^{p-2} \\
&\quad \times (u(\bar{x}) + \kappa\beta(\bar{x}) - u(\bar{x} + y) - \kappa\beta(\bar{x} + y)) K_{sp}(\bar{x}, y) \, dy,
\end{aligned}$$

$$I_2^q := \int_{\bar{x}+y \notin B_1} \hat{c}a(\bar{x}, y) |u(\bar{x}) + \kappa\beta(\bar{x}) - u(\bar{x} + y) - \kappa\beta(\bar{x} + y)|^{q-2} \\ (u(\bar{x}) + \kappa\beta(\bar{x}) - u(\bar{x} + y) - \kappa\beta(\bar{x} + y)) K_{tq}(\bar{x}, y) dy.$$

Being $q \geq 2$, the estimates for terms I_1^q, I_2^q are the same as those in the previous case, therefore we have

$$(4.21) \quad I_1^q \leq 2^{q-2} \int_{\bar{x}+y \in B_1} \hat{c}a(\bar{x}, y) |u(\bar{x}) - u(\bar{x} + y)|^{q-2} (u(\bar{x}) - u(\bar{x} + y)) K_{tq}(\bar{x}, y) dy \\ + 2^{q-2} \kappa^{q-1} \int_{\bar{x}+y \in B_1} \hat{c}a(\bar{x}, y) |\beta(\bar{x}) - \beta(\bar{x} + y)|^{q-1} K_{tq}(\bar{x}, y) dy$$

and

$$(4.22) \quad I_2^q \leq 2^{q-2} \int_{\bar{x}+y \notin B_1} \hat{c}a(\bar{x}, y) |u(\bar{x}) - u(\bar{x} + y)|^{q-2} (u(\bar{x}) - u(\bar{x} + y)) K_{tq}(\bar{x}, y) dy \\ + 2^{q-2} \int_{\bar{x}+y \notin B_1} \hat{c}a(\bar{x}, y) |\kappa\beta(\bar{x}) - \kappa\beta(\bar{x} + y) + 2(|2(\bar{x} + y)|^\eta - 1)|^{q-2} \\ \times (\kappa\beta(\bar{x}) - \kappa\beta(\bar{x} + y) + 2(|2(\bar{x} + y)|^\eta - 1)) K_{tq}(\bar{x}, y) dy.$$

Since $p \leq 2$ and $q \geq 2$, we can use (4.18), (4.19) and Lemma 4 to get

$$\left| u(\bar{x}) + \kappa\beta(\bar{x}) - u(\bar{x} + y) - \kappa\beta(\bar{x} + y) \right|^{p-2} \left(u(\bar{x}) + \kappa\beta(\bar{x}) - u(\bar{x} + y) - \kappa\beta(\bar{x} + y) \right) \\ \leq 2^{q-2} |u(\bar{x}) - u(\bar{x} + y)|^{p-2} (u(\bar{x}) - u(\bar{x} + y)) \\ + (6^{q-1} + 2^{2q-3}) \kappa^{p-1} |\beta(\bar{x}) - \beta(\bar{x} + y)|^{p-1}$$

and

$$(4.23) \quad \left| u(\bar{x}) + \kappa\beta(\bar{x}) - u(\bar{x} + y) - \kappa\beta(\bar{x} + y) + 2(|2(\bar{x} + y)|^\eta - 1) \right|^{p-2} \\ \times \left(u(\bar{x}) + \kappa\beta(\bar{x}) - u(\bar{x} + y) - \kappa\beta(\bar{x} + y) + 2(|2(\bar{x} + y)|^\eta - 1) \right) \\ \leq 2^{q-2} |u(\bar{x}) - u(\bar{x} + y)|^{p-2} (u(\bar{x}) - u(\bar{x} + y)) \\ + (6^{q-1} + 2^{2q-3}) \left| \kappa\beta(\bar{x}) - \kappa\beta(\bar{x} + y) + 2(|2(\bar{x} + y)|^\eta - 1) \right|^{p-1}.$$

Finally, we can conclude that

$$(4.24) \quad I_1 \stackrel{(4.21), (4.19)}{\leq} 2^{q-2} \int_{\bar{x}+y \in B_1} |u(\bar{x}) - u(\bar{x} + y)|^{p-2} (u(\bar{x}) - u(\bar{x} + y)) K_{sp}(\bar{x}, y) dy \\ + 2^{q-2} \int_{\bar{x}+y \in B_1} \hat{c}a(\bar{x}, y) |u(\bar{x}) - u(\bar{x} + y)|^{q-2} (u(\bar{x}) - u(\bar{x} + y)) K_{tq}(\bar{x}, y) dy \\ + (6^{q-1} + 2^{2q-3}) \kappa^{p-1} \int_{\bar{x}+y \in B_1} |\beta(\bar{x}) - \beta(\bar{x} + y)|^{p-1} K_{sp}(\bar{x}, y) dy \\ + 2^{q-2} \kappa^{q-1} \int_{\bar{x}+y \in B_1} \hat{c}a(\bar{x}, y) |\beta(\bar{x}) - \beta(\bar{x} + y)|^{q-2} (\beta(\bar{x}) - \beta(\bar{x} + y)) K_{tq}(\bar{x}, y) dy$$

and

$$\begin{aligned}
I_2 &\stackrel{(4.22),(4.23)}{\leq} 2^{q-2} \int_{\bar{x}+y \notin B_1} |u(\bar{x}) - u(\bar{x}+y)|^{p-2} (u(\bar{x}) - u(\bar{x}+y)) K_{sp}(\bar{x}, y) \, dy \\
&\quad + 2^{q-2} \int_{\bar{x}+y \notin B_1} \hat{c}a(\bar{x}, y) |u(\bar{x}) - u(\bar{x}+y)|^{q-2} (u(\bar{x}) - u(\bar{x}+y)) K_{tq}(\bar{x}, y) \, dy \\
&\quad + (6^{q-1} + 2^{2q-3}) \int_{\bar{x}+y \notin B_1} \left| \kappa\beta(\bar{x}) - \kappa\beta(\bar{x}+y) + 2 \left(|2(\bar{x}+y)|^\eta - 1 \right) \right|^{p-1} K_{sp}(\bar{x}, y) \, dy \\
&\quad + 2^{q-2} \int_{\bar{x}+y \notin B_1} \hat{c}a(\bar{x}, y) \left| \kappa\beta(\bar{x}) - \kappa\beta(\bar{x}+y) + 2 \left(|2(\bar{x}+y)|^\eta - 1 \right) \right|^{q-2} \\
(4.25) \quad &\quad \times \left(\kappa\beta(\bar{x}) - \kappa\beta(\bar{x}+y) + 2 \left(|2(\bar{x}+y)|^\eta - 1 \right) \right) K_{tq}(\bar{x}, y) \, dy,
\end{aligned}$$

so that

$$\begin{aligned}
&\mathcal{L}(u + \kappa\beta)(\bar{x}) \\
&\stackrel{(4.24),(4.25)}{\leq} 2^{q-2} \mathcal{L}u(\bar{x}) + (6^{q-1} + 2^{2q-3}) \kappa^{p-1} \int_{\bar{x}+y \in B_1} |\beta(\bar{x}) - \beta(\bar{x}+y)|^{p-1} K_{sp}(\bar{x}, y) \, dy \\
&\quad + 2^{q-2} \kappa^{q-1} \int_{\bar{x}+y \in B_1} \hat{c}a(\bar{x}, y) |\beta(\bar{x}) - \beta(\bar{x}+y)|^{q-2} (\beta(\bar{x}) - \beta(\bar{x}+y)) K_{tq}(\bar{x}, y) \, dy \\
&\quad + (6^{q-1} + 2^{2q-3}) \int_{\bar{x}+y \notin B_1} \left| \kappa\beta(\bar{x}) - \kappa\beta(\bar{x}+y) + 2 \left(|2(\bar{x}+y)|^\eta - 1 \right) \right|^{p-1} K_{sp}(\bar{x}, y) \, dy \\
&\quad + 2^{q-2} \int_{\bar{x}+y \notin B_1} \left(\hat{c}a(\bar{x}, y) \left| \kappa\beta(\bar{x}) - \kappa\beta(\bar{x}+y) + 2 \left(|2(\bar{x}+y)|^\eta - 1 \right) \right|^{q-2} \right. \\
&\quad \quad \left. \times \left(\kappa\beta(\bar{x}) - \kappa\beta(\bar{x}+y) + 2 \left(|2(\bar{x}+y)|^\eta - 1 \right) \right) K_{tq}(\bar{x}, y) \right) \, dy \\
&\stackrel{(4.16)}{\leq} 2^{q-2} \sigma + (6^{q-1} + 2^{2q-3}) \kappa^{p-1} \int_{\bar{x}+y \in B_1} |\beta(\bar{x}) - \beta(\bar{x}+y)|^{p-1} K_{sp}(\bar{x}, y) \, dy \\
&\quad + 2^{q-2} \kappa^{q-1} \int_{\bar{x}+y \in B_1} \hat{c}a(\bar{x}, y) |\beta(\bar{x}) - \beta(\bar{x}+y)|^{q-1} K_{tq}(\bar{x}, y) \, dy \\
&\quad + (6^{q-1} + 2^{2q-3}) \int_{\bar{x}+y \notin B_1} \left| \kappa\beta(\bar{x}) - \kappa\beta(\bar{x}+y) + 2 \left(|2(\bar{x}+y)|^\eta - 1 \right) \right|^{p-1} K_{sp}(\bar{x}, y) \, dy \\
(4.26) \quad &\quad + 2^{q-2} \int_{\bar{x}+y \notin B_1} \hat{c}a(\bar{x}, y) \left| \kappa\beta(\bar{x}) - \kappa\beta(\bar{x}+y) + 2 \left(|2(\bar{x}+y)|^\eta - 1 \right) \right|^{q-1} K_{tq}(\bar{x}, y) \, dy.
\end{aligned}$$

Recalling the definition of σ and combining (4.26), (4.17), (4.4), we obtain

$$\begin{aligned}
\frac{\varepsilon}{\Lambda 2^{n+sp+q-1}} &\leq 2^{q-1}(2^{q-2} + \hat{c}M) \int_{y \notin B_{1/4}} (|8y|^\eta - 1)^{p-1} K_{sp}(\bar{x}, y) + (|8y|^\eta - 1)^{q-1} K_{tq}(\bar{x}, y) \, dy \\
&\quad + (6^{q-1} + 2^{2q-3}) \kappa^{p-1} \int_{\bar{x}+y \in B_1} |\beta(\bar{x}) - \beta(\bar{x} + y)|^{p-1} K_{sp}(\bar{x}, y) \, dy \\
&\quad + 2^{q-2} \kappa^{q-1} \int_{\bar{x}+y \in B_1} \hat{c}a(\bar{x}, y) |\beta(\bar{x}) - \beta(\bar{x} + y)|^{q-1} K_{tq}(\bar{x}, y) \, dy \\
&\quad + (6^{q-1} + 2^{2q-3}) \int_{\bar{x}+y \notin B_1} |\kappa\beta(\bar{x}) - \kappa\beta(\bar{x} + y) + 2(|2(\bar{x} + y)|^\eta - 1)|^{p-1} K_{sp}(\bar{x}, y) \, dy \\
&\quad + 2^{q-2} \int_{\bar{x}+y \notin B_1} \hat{c}a(\bar{x}, y) |\kappa\beta(\bar{x}) - \kappa\beta(\bar{x} + y) + 2(|2(\bar{x} + y)|^\eta - 1)|^{q-1} K_{tq}(\bar{x}, y) \, dy \\
&\leq \frac{\varepsilon}{\Lambda 2^{n+sp+q}},
\end{aligned}$$

which again is a contradiction.

Case 3: $2 \geq q > 1/(1-t)$ and $2 \geq p > 1/(1-s)$. In this case, we first use Lemma 4 to get, for $r = \{p, q\}$,

$$\begin{aligned}
&|u(\bar{x}) + \kappa\beta(\bar{x}) - u(\bar{x} + y) - \kappa\beta(\bar{x} + y)|^{r-2} \left(u(\bar{x}) + \kappa\beta(\bar{x}) - u(\bar{x} + y) - \kappa\beta(\bar{x} + y) \right) \\
&\leq |u(\bar{x}) - u(\bar{x} + y)|^{r-2} (u(\bar{x}) - u(\bar{x} + y)) + (3^{q-1} + 2^{q-1}) \kappa^{r-1} |\beta(\bar{x}) - \beta(\bar{x} + y)|^{r-1}
\end{aligned}$$

and so,

$$\begin{aligned}
&|u(\bar{x}) + \kappa\beta(\bar{x}) - u(\bar{x} + y) - \kappa\beta(\bar{x} + y) + 2(|2(\bar{x} + y)|^\eta - 1)|^{r-2} \\
&\quad \times (u(\bar{x}) + \kappa\beta(\bar{x}) - u(\bar{x} + y) - \kappa\beta(\bar{x} + y) + 2(|2(\bar{x} + y)|^\eta - 1)) \\
&\leq |u(\bar{x}) - u(\bar{x} + y)|^{r-2} (u(\bar{x}) - u(\bar{x} + y)) \\
&\quad + (3^{q-1} + 2^{q-1}) |\kappa\beta(\bar{x}) - \kappa\beta(\bar{x} + y) + 2(|2(\bar{x} + y)|^\eta - 1)|^{r-1}.
\end{aligned}$$

Thus, by combining the two estimates above, we get

$$\begin{aligned}
I_1 &\leq \int_{\bar{x}+y \in B_1} |u(\bar{x}) - u(\bar{x} + y)|^{p-2} (u(\bar{x}) - u(\bar{x} + y)) K_{sp}(\bar{x}, y) \, dy \\
&\quad + \int_{\bar{x}+y \in B_1} \hat{c}a(\bar{x}, y) |u(\bar{x}) - u(\bar{x} + y)|^{q-2} (u(\bar{x}) - u(\bar{x} + y)) K_{tq}(\bar{x}, y) \, dy \\
&\quad + (3^{q-1} + 2^{q-1}) \kappa^{p-1} \int_{\bar{x}+y \in B_1} |\beta(\bar{x}) - \beta(\bar{x} + y)|^{p-1} K_{sp}(\bar{x}, y) \, dy \\
(4.27) \quad &\quad + (3^{q-1} + 2^{q-1}) \kappa^{q-1} \int_{\bar{x}+y \in B_1} \hat{c}a(\bar{x}, y) |\beta(\bar{x}) - \beta(\bar{x} + y)|^{q-1} K_{tq}(\bar{x}, y) \, dy
\end{aligned}$$

and

$$\begin{aligned}
I_2 &\leq \int_{\bar{x}+y \notin B_1} |u(\bar{x}) - u(\bar{x} + y)|^{p-2} (u(\bar{x}) - u(\bar{x} + y)) K_{sp}(\bar{x}, y) \, dy \\
&\quad + \int_{\bar{x}+y \notin B_1} \hat{c}a(\bar{x}, y) |u(\bar{x}) - u(\bar{x} + y)|^{q-2} (u(\bar{x}) - u(\bar{x} + y)) K_{tq}(\bar{x}, y) \, dy \\
&\quad + (3^{q-1} + 2^{q-1}) \int_{\bar{x}+y \notin B_1} |\kappa\beta(\bar{x}) - \kappa\beta(\bar{x} + y) + 2(|2(\bar{x} + y)|^\eta - 1)|^{p-1} K_{sp}(\bar{x}, y) \, dy \\
(4.28) \quad &\quad + (3^{q-1} + 2^{q-1}) \int_{\bar{x}+y \notin B_1} \hat{c}a(\bar{x}, y) |\kappa\beta(\bar{x}) - \kappa\beta(\bar{x} + y) + 2(|2(\bar{x} + y)|^\eta - 1)|^{q-1} K_{tq}(\bar{x}, y) \, dy,
\end{aligned}$$

therefore

$$\begin{aligned}
&\mathcal{L}(u + \kappa\beta)(\bar{x}) \\
&\stackrel{(4.27), (4.28)}{\leq} \mathcal{L}u(\bar{x}) + (3^{q-1} + 2^{q-1}) \kappa^{p-1} \int_{\bar{x}+y \in B_1} |\beta(\bar{x}) - \beta(\bar{x} + y)|^{p-1} K_{sp}(\bar{x}, y) \, dy \\
&\quad + (3^{q-1} + 2^{q-1}) \kappa^{q-1} \int_{\bar{x}+y \in B_1} \hat{c}a(\bar{x}, y) |\beta(\bar{x}) - \beta(\bar{x} + y)|^{q-1} K_{tq}(\bar{x}, y) \, dy \\
&\quad + (3^{q-1} + 2^{q-1}) \int_{\bar{x}+y \notin B_1} |\kappa\beta(\bar{x}) - \kappa\beta(\bar{x} + y) + 2(|2(\bar{x} + y)|^\eta - 1)|^{p-1} K_{sp}(\bar{x}, y) \, dy \\
&\quad + (3^{q-1} + 2^{q-1}) \int_{\bar{x}+y \notin B_1} \hat{c}a(\bar{x}, y) |\kappa\beta(\bar{x}) - \kappa\beta(\bar{x} + y) + 2(|2(\bar{x} + y)|^\eta - 1)|^{q-1} K_{tq}(\bar{x}, y) \, dy \\
&\stackrel{(4.16)}{\leq} \sigma + (3^{q-1} + 2^{q-1}) \kappa^{p-1} \int_{\bar{x}+y \in B_1} |\beta(\bar{x}) - \beta(\bar{x} + y)|^{p-1} K_{sp}(\bar{x}, y) \, dy \\
&\quad + (3^{q-1} + 2^{q-1}) \kappa^{q-1} \int_{\bar{x}+y \in B_1} \hat{c}a(\bar{x}, y) |\beta(\bar{x}) - \beta(\bar{x} + y)|^{q-1} K_{tq}(\bar{x}, y) \, dy \\
&\quad + (3^{q-1} + 2^{q-1}) \int_{\bar{x}+y \notin B_1} |\kappa\beta(\bar{x}) - \kappa\beta(\bar{x} + y) + 2(|2(\bar{x} + y)|^\eta - 1)|^{p-1} K_{sp}(\bar{x}, y) \, dy \\
&\quad + (3^{q-1} + 2^{q-1}) \int_{\bar{x}+y \notin B_1} \hat{c}a(\bar{x}, y) \left| \kappa\beta(\bar{x}) - \kappa\beta(\bar{x} + y) + 2(|2(\bar{x} + y)|^\eta - 1) \right|^{q-1} K_{tq}(\bar{x}, y) \, dy.
\end{aligned}$$

Merging the content of the above display with (4.17) and using (4.5), we reach the following contradiction:

$$\begin{aligned}
\frac{\varepsilon}{\Lambda 2^{n+sp+q-1}} &\leq 2^{q-1}(1 + \hat{c}M) \int_{y \notin B_{1/4}} (|8y|^\eta - 1)^{p-1} K_{sp}(\bar{x}, y) + (|8y|^\eta - 1)^{q-1} K_{tq}(\bar{x}, y) \, dy \\
&\quad + (3^{q-1} + 2^{q-1}) \kappa^{p-1} \int_{\bar{x}+y \in B_1} |\beta(\bar{x}) - \beta(\bar{x} + y)|^{p-1} K_{sp}(\bar{x}, y) \, dy \\
&\quad + (3^{q-1} + 2^{q-1}) \kappa^{q-1} \int_{\bar{x}+y \in B_1} \hat{c}a(\bar{x}, y) |\beta(\bar{x}) - \beta(\bar{x} + y)|^{q-1} K_{tq}(\bar{x}, y) \, dy \\
&\quad + (3^{q-1} + 2^{q-1}) \int_{\bar{x}+y \notin B_1} |\kappa\beta(\bar{x}) - \kappa\beta(\bar{x} + y) + 2(|2(\bar{x} + y)|^\eta - 1)|^{p-1} K_{sp}(\bar{x}, y) \, dy \\
&\quad + (3^{q-1} + 2^{q-1}) \int_{\bar{x}+y \notin B_1} \hat{c}a(\bar{x}, y) \left| \kappa\beta(\bar{x}) - \kappa\beta(\bar{x} + y) + 2(|2(\bar{x} + y)|^\eta - 1) \right|^{q-1} \\
&\quad \quad \quad \times K_{tq}(\bar{x}, y) \, dy \\
&\leq \frac{\varepsilon}{\Lambda 2^{n+sp+q}}.
\end{aligned}$$

□

5. HÖLDER CONTINUITY

This section is devoted to the proof of the Hölder continuity of the solutions, namely Theorem 1. As in the local framework, at this stage, an iteration lemma will be the keypoint of the proof. However, as before, we have to handle the nonlocality of the involved operators together with the modulating function $a(\cdot, \cdot)$, and thus a certain care is required. Also, the scaling behavior of the nonlocal double phase equations has to be taking into account, precisely when dealing with the datum f in order to apply the result in Lemma 1. Here, as expected, the assumptions on the summability exponents (2.4)-(2.5) will be in force, in clear accordance with the observation in Remark 1; for further clarification in this respect we refer to forthcoming Sections 5.2-5.3. On the whole, in the proof below, all the estimates proven in the previous section will take part.

5.1. Proof of Theorem 1. Let u be a solution of problem (2.1), with \mathcal{L} as in (2.2), under assumptions (2.3)–(2.7). For a small parameter σ chosen as in (4.14), we first rescale u by defining the map $\tilde{u} := \lambda u$, where

$$(5.1) \quad \lambda := \frac{1}{2} \left(\frac{1}{\|u\|_{L^\infty} + (\|f\|_{L^\infty(B_2)}/\sigma)^{1/(p-1)}} \right).$$

From (5.1), it is easy to see that

$$\operatorname{osc}_{\mathbb{R}^n} u \leq 1$$

and, according to the scaling properties of \mathcal{L} discussed in the Appendix at Page 29, the function \tilde{u} satisfies

$$\tilde{\mathcal{L}}\tilde{u} = \tilde{f} \text{ in } B_2,$$

where $\tilde{\mathcal{L}}$ is an operator of the type of those considered in (4.1), precisely

$$\begin{aligned} \tilde{\mathcal{L}}v(x) &:= \int_{\mathbb{R}^n} |v(x) - v(x+y)|^{p-2} (v(x) - v(x+y)) K_{sp}(x, y) \, dy \\ &\quad + \int_{\mathbb{R}^n} \lambda^{p-q} a(x, y) |v(x) - v(x+y)|^{q-2} (v(x) - v(x+y)) K_{tq}(x, y) \, dy \end{aligned}$$

and

$$\tilde{f}(x) := \lambda^{p-1} f(x),$$

for $x \in B_2$. Again, the definition in (5.1) assures that

$$\|\tilde{f}\|_{L^\infty(B_2)} \leq \frac{\sigma}{2^{p-1}}.$$

Now, fix $x_0 \in B_1$. For $i \in \mathbb{Z}$, by induction, we are going to find b_i, c_i so that

$$(5.2) \quad b_i \leq \tilde{u}(x) \leq c_i \quad \text{in } B_{2^{-i}}(x_0) \quad \text{and} \quad |c_i - b_i| \leq 2^{-i\gamma},$$

where $\gamma \in (0, 1)$ satisfies

$$(5.3) \quad \frac{2-\theta}{2} \leq 2^{-\gamma} \quad \text{and} \quad \gamma \leq \eta < \min \left\{ \frac{sp}{p-1}, \frac{tq}{q-1} \right\}.$$

The values of $\theta = \theta(\text{data})$ and $\eta = \eta(\text{data})$ are those coming from Proposition 2 and Lemma 1 corresponding to $\varepsilon = |B_1|/2$. Clearly, (5.2) is satisfied for $i \leq 0$ by the choice $b_i := \inf_{x \in \mathbb{R}^n} u(x)$ and $c_i := b_i + 1$. Let us assume that (5.2) holds for $i \leq j$, by induction we will construct b_{j+1} and c_{j+1} . Consider the function \bar{u} defined as follows:

$$\bar{u}(x) := 2^{\gamma j+1} \left(\tilde{u}(2^{-j}x + x_0) - m \right), \quad \text{for } x \in B_1,$$

where $m := (b_j + c_j)/2$. By (5.2) and (5.1), it is evident that $\|\bar{u}\|_{L^\infty(B_1)} \leq 1$ and, invoking again the behavior of the operator \mathcal{L} under blow up, we obtain that \bar{u} solves

$$\bar{\mathcal{L}}\bar{u} = \bar{f} \quad \text{in } B_1,$$

where

$$\begin{aligned} \bar{\mathcal{L}}v(x) &:= \int_{\mathbb{R}^n} |v(x) - v(x+y)|^{p-2} (v(x) - v(x+y)) \bar{K}_{sp}(x, y) \, dy \\ &\quad + \int_{\mathbb{R}^n} \bar{a}(x, y) |v(x) - v(x+y)|^{q-2} (v(x) - v(x+y)) \bar{K}_{tq}(x, y) \, dy \end{aligned} \quad (5.4)$$

and

$$\bar{f}(x) := \lambda^{p-1} 2^{(\gamma j+1)(p-1)-j sp} f(2^{-j}x + x_0).$$

From (5.1) and (5.3)₂ it follows that

$$(5.5) \quad \|\bar{f}\|_{L^\infty(B_1)} \leq \sigma.$$

Notice also that in (5.4), the kernels $\bar{K}_{sp}(\cdot, \cdot)$ and $\bar{K}_{tq}(\cdot, \cdot)$ are given by

$$(5.6) \quad \begin{cases} \bar{K}_{sp}(x, y) := 2^{-j(n+sp)} K_{sp}(2^{-j}x + x_0, 2^{-j}y) \\ \bar{K}_{tq}(x, y) := 2^{-j(n+tq)} K_{tq}(2^{-j}x + x_0, 2^{-j}y) \end{cases},$$

so that (2.3) is satisfied. Moreover, the new modulating coefficient is given by

$$(5.7) \quad \bar{a}(x, y) := \lambda^{p-q} 2^{-j(sp-tq)+(\gamma j+1)(p-q)} a(2^{-j}x + x_0, 2^{-j}y).$$

As to verify (2.6) for $\bar{a}(\cdot, \cdot)$, we need to analyze the behavior of λ , which is ultimately influenced only by σ . Therefore, using (4.14) we obtain that

$$\begin{aligned}
\sigma^- &:= \frac{\omega_n 2^{q-1+2sp}(2^\eta - 1)}{sp} \\
&\leq \sigma \\
(5.8) \quad &\leq \omega_n 2^{q+3\eta(q-1)} \max \left\{ \frac{4^{sp-\eta(p-1)}}{sp-\eta(p-1)}, \frac{4^{tq-\eta(q-1)}}{tq-\eta(q-1)} \right\} =: \sigma^+,
\end{aligned}$$

where η is by now fixed. Coupling (5.7), (2.6), (5.1), (2.5), (5.8), and recalling that $\sigma \ll 1$, we can conclude that

$$\begin{aligned}
\|\bar{a}\|_{L^\infty(B_1)} &\leq 2^{q-p} M \left(\|u\|_{L^\infty(\mathbb{R}^n)} + \left(\frac{\|f\|_{L^\infty(B_2)}}{\sigma} \right)^{\frac{1}{p-1}} \right)^{q-p} \\
(5.9) \quad &\leq c(\sigma^-)^{\frac{p-q}{p-1}} =: \bar{M}(\mathbf{data}),
\end{aligned}$$

for a constant c depending only on $p, q, M, \|u\|_{L^\infty(\mathbb{R}^n)}, \|f\|_{L^\infty(B_2)}$, so that (2.6) is satisfied as well.

Finally, we notice that, given any $y \in \mathbb{R}^n \setminus B_1$, there is an integer $\ell \geq 0$ such that $2^\ell \leq |y| \leq 2^{\ell+1}$, so we have

$$\begin{aligned}
\bar{u}(y) &= 2^{\gamma j+1} \left(\tilde{u}(2^{-j}y + x_0) - m \right) \leq 2^{\gamma j+1} (c_{j-\ell-1} - m) \\
&\leq 2^{\gamma j+1} (c_{j-\ell-1} + b_j - b_{j-\ell-1} - m) \\
&\leq 2^{\gamma j+1} \left(2^{-\gamma(j-\ell-1)} + b_j - m \right) \leq 2^{\gamma j+1} \left(2^{-\gamma(j-\ell-1)} - 2^{-(\gamma j+1)} \right) \\
&\leq 2^{1+\gamma(\ell+1)} - 1 \leq 2|2y|^\gamma - 1 \leq 2|2y|^\eta - 1,
\end{aligned}$$

where we also used that the inductive step (5.2) holds for $i \leq j$ and (5.3)₂. It is not restrictive now to suppose that $|\{x \in B_1 : \bar{u}(x) \leq 0\}| \geq |B_1|/2$, (otherwise we can apply the same procedure to $-\bar{u}$); collecting estimates (5.5), (5.6) and (5.9) we see that $\bar{\mathcal{L}}, \bar{u}$ and \bar{f} satisfy all the assumptions of Lemma 1 corresponding to $\varepsilon = |B_1|/2$. As a consequence, $\bar{u}(x) \leq 1 - \theta$ in $B_{1/2}$, for some $\theta = \theta(\mathbf{data})$. Scaling back to \tilde{u} , this renders

$$\begin{aligned}
\tilde{u}(x) &\leq 2^{-(\gamma j+1)}(1 - \theta) + m = 2^{-(\gamma j+1)}(1 - \theta) + \frac{b_j + c_j}{2} \\
&\leq b_j + 2^{-(1+\gamma j)}(1 - \theta) + 2^{-(1+\gamma j)} \\
&\leq b_j + 2^{-\gamma(j+1)},
\end{aligned}$$

where we used the definition of m , (5.2)₂ and (5.3)₁. Hence, the choices $b_{j+1} = b_j$ and $c_{j+1} = b_j + 2^{-\gamma(j+1)}$ fix (5.2) for step $i = j + 1$. Now, for any $\varrho \in (0, 1)$ we can find an integer $j \geq 0$ so that $2^{-j-1} \leq \varrho \leq 2^{-j}$ and

$$\begin{aligned}
\operatorname{osc}_{B_\varrho(x_0)} \tilde{u} &= \sup_{x \in B_\varrho(x_0)} \tilde{u}(x) - \inf_{x \in B_\varrho(x_0)} \tilde{u}(x) \\
&\leq b_{j-1} + 2^{-\gamma j} - b_{j-1} \leq 2^\gamma 2^{-\gamma(j+1)} \leq 2^\gamma \varrho^\gamma.
\end{aligned}$$

Scaling back to u in the previous estimate and recalling (5.1) and (5.8), we have that

$$\begin{aligned} \operatorname{osc}_{B_\varrho(x_0)} u &\leq \varrho^\gamma 2^{\gamma+1} \left(\|u\|_{L^\infty(\mathbb{R}^n)} + \left(\frac{\|f\|_{L^\infty(B_2)}}{\sigma^-} \right)^{\frac{1}{p-1}} \right) \\ &\leq c(\mathbf{data}) \left(\|u\|_{L^\infty(\mathbb{R}^n)} + \|f\|_{L^\infty(B_2)}^{\frac{1}{p-1}} \right) \varrho^\gamma. \end{aligned}$$

Here, of course, $\gamma = \gamma(\mathbf{data})$. By standard covering, we can finally conclude that $u \in C^{0,\gamma}(B_1)$, as desired.

5.2. Further clarification. In the proof of Theorem 1, a crucial role is played by the estimates in Proposition 2. However, in the light of the scaling features of the operator \mathcal{L} , it is evident that, while reducing σ by sending $\eta \rightarrow 0^+$ there is some competition among the terms appearing in estimates (4.3)–(4.5). Adopting the same terminology of Proposition 2, from (5.1) and (5.7), we see that

$$\hat{c} \leq \tilde{\lambda}^{p-q} \quad \text{and} \quad \lambda^{p-q} \sim \sigma^{-\frac{q-p}{p-1}},$$

where the constants implicit in “ \sim ” depend only on $p, q, \|f\|_{L^\infty(B_2)}, \|u\|_{L^\infty(\mathbb{R}^n)}$. Thus, recalling (4.3), we look at those terms depending on η and we can estimate

$$\begin{aligned} &2^{2p+q-6} \int_{x+y \notin B_1} \left| |2(x+y)|^\eta - 1 \right|^{p-1} K_{sp}(x, y) \, dy \\ &+ (2 + \hat{c}M) 2^{q-1} \int_{y \notin B_{1/4}} \left((|8y|^\eta - 1)^{p-1} K_{sp}(x, y) + (|8y|^\eta - 1)^{q-1} K_{tq}(x, y) \right) \, dy \\ &\leq \left(2^{2p-4} \Lambda + \hat{c}M \right) 2^{q-1} \int_{y \notin B_{1/4}} \left((|8y|^\eta - 1)^{p-1} K_{sp}(x, y) + (|8y|^\eta - 1)^{q-1} K_{tq}(x, y) \right) \, dy \\ (5.10) \quad &\leq c\sigma^{1-\frac{q-p}{p-1}}, \end{aligned}$$

since $|x|$ is supposed to be less than $3/4$ in the proofs of Proposition 2 and of Lemma 1. Here, $c = c(\mathbf{data})$. Condition (2.5) yields that the exponent of the term in the right-hand side of (5.10) is strictly positive, so we can find a sufficiently small $\eta_1 > 0$ so that $c\sigma^{1-\frac{q-p}{p-1}} \leq \varepsilon/(5\Lambda 2^{n+sp+q+1})$. Fixed η_1 , we can complete the bound on those terms appearing on the left-hand side of (4.3) as follows

$$\begin{aligned} &2^{q-2} \kappa_1^{p-1} \int_{x+y \in B_1} |\beta(x) - \beta(x+y)|^{p-1} K_{sp}(x, y) \, dy \\ &+ 2^{q-2} \kappa_1^{q-1} \int_{x+y \in B_1} \hat{c}a(x, y) |\beta(x) - \beta(x+y)|^{q-1} K_{tq}(x, y) \, dy \\ &+ 2^{p+q-4} \kappa_1^{p-1} \int_{x+y \notin B_1} |\beta(x) - \beta(x, y)|^{p-1} K_{sp}(x, y) \, dy \\ &+ 2^{2q-4} \kappa_1^{q-1} \int_{x+y \notin B_1} \hat{c}a(x, y) |\beta(x) - \beta(x, y)|^{q-1} K_{tq}(x, y) \, dy \\ (5.11) \quad &\leq c \left(\kappa_1^{p-1} + \sigma^{-\frac{q-p}{p-1}} \kappa_1^{q-1} \right) \leq \frac{\varepsilon}{5\Lambda 2^{n+sp+q+1}}, \end{aligned}$$

provided that $\kappa_1 \leq \left(\frac{\sigma}{2c}\right)^{\frac{1}{p-1}}$, with $c = c(\mathbf{data})$. Then, we can easily deduce inequality (4.3) by merging the contents of (5.10) and (5.11). In a totally similar way we can manipulate the quantities appearing in (4.4) and in (4.5) as to verify those bounds and, at the same time, avoid any competition among the parameters involved.

Now, we let η_2, κ_2 and η_3, κ_3 be those values of η and of κ for which (4.4) and (4.5) hold respectively, and finally set $\eta := \min\{\eta_1, \eta_2, \eta_3\}$ and $\kappa := \min\{\kappa_1, \kappa_2, \kappa_3\}$. In this way, (4.3)–(4.5) are simultaneously satisfied. Notice that $\eta = \eta(\mathbf{data}, \varepsilon)$ and $\kappa = \kappa(\mathbf{data}, \varepsilon)$.

APPENDIX

We complete this paper by discussing some intrinsic characteristics of the class of operators under investigation.

5.3. Scaling properties of the nonlocal double phase equations. Let us analyze the structure of operator \mathcal{L} by investigating some general scaling properties. Under assumption (2.7), let $u \in L^\infty(\mathbb{R}^n)$ be a viscosity solution to problem (2.1) in the sense of Definition 1. We rescale and blow u around a point $x_0 \in B_1$ as follows. For $\lambda, \mu > 0$ and $x \in B_1$, we define the map $u_{\mu, x_0}^{(\lambda)}(x) := \lambda u(\mu x + x_0)$. Such a function satisfies

$$\hat{\mathcal{L}}u_{\mu, x_0}^{(\lambda)}(x) := \hat{f}(x) \quad \text{in } B_1,$$

where

$$\begin{aligned} \hat{\mathcal{L}}v(x) &:= \int_{\mathbb{R}^n} |v(x) - v(x+y)|^{p-2} (v(x) - v(x+y)) \hat{K}_{sp}(x, y) \, dy \\ (5.12) \quad &+ \int_{\mathbb{R}^n} \hat{a}(x, y) |v(x) - v(x+y)|^{q-2} (v(x) - v(x+y)) \hat{K}_{tq}(x, y) \, dy \end{aligned}$$

and

$$(5.13) \quad \hat{f}(x) := \lambda^{p-1} \mu^{sp} f(\mu x + x_0).$$

The modulating coefficient and the kernels appearing in (5.12) are defined as

$$(5.14) \quad \hat{a}(x, y) := \lambda^{p-q} \mu^{sp-tq} a(\mu x + x_0, \mu y)$$

and

$$(5.15) \quad \begin{cases} \hat{K}_{sp}(x, y) := \mu^{n+sp} K_{sp}(\mu x + x_0, \mu y) \\ \hat{K}_{tq}(x, y) := \mu^{n+tq} K_{tq}(\mu x + x_0, \mu y) \end{cases},$$

respectively. From (5.15), it immediately follows that \hat{K}_{sp} and \hat{K}_{tq} satisfy (2.3). Moreover, (5.14) yields (2.6) via replacing M with $\hat{M} := \lambda^{p-q} \mu^{sp-tq} M$ and, by (5.13) it follows that $\|\hat{f}\|_{L^\infty(B_1)} \leq \lambda^{p-1} \mu^{sp-tq} \|f\|_{L^\infty(B_1)}$.

5.4. Some useful inequalities. We report some elementary algebraic inequalities whose proofs are essentially contained in the Appendix in [26]; see in particular Lemma 3 and Lemma 4 there. We refer also to Section 2 in [22] where similar inequalities do appear. All of them are very useful in estimating the p -fractional Sobolev seminorms, and they were needed in the whole paper. For the sake of completeness, here below we address the plain modifications in order to extend them to the fractional (p, q) -growth case.

Lemma 2. *Let $r \geq 2$, $r \in \{p, q\}$. Then*

$$\left| |a + b|^{r-2}(a + b) - |a|^{r-2}a \right| \leq (r - 1)|b|(|a| + |b|)^{r-2},$$

for all $a, b \in \mathbb{R}$.

Proof. The proof is contained in [26, Lemma 2]. \square

Lemma 3. *Let $q \geq p \geq 2$ and let $a, b \in \mathbb{R}$ such that $a + b \geq 0$. Then, for $r \in \{p, q\}$ there holds*

$$|a + b|^{r-2}(a + b) \leq 2^{q-2}(|a|^{r-2}a + |b|^{r-2}b).$$

Proof. Firstly, notice that, $a + b \geq 0$ implies $|a|^{r-2}a + |b|^{r-2}b \geq 0$ and, by homogeneity, the statement is equivalent to $|1 + \tau|^{r-2}(1 + \tau) \leq 2^{r-2}(1 + |\tau|^{r-2}\tau)$ with $\tau \geq -1$ and $r \in \{p, q\}$. For this, it will suffice to study the asymptotics of the function $\tau \mapsto f_r(\tau) := \frac{|1 + \tau|^{r-2}(1 + \tau)}{1 + |\tau|^{r-2}\tau}$ for $\tau \geq -1$. It is easy to check that $f_r(\tau) \leq 2^{r-2} \leq 2^{q-2}$, and this will give the desired inequality. \square

Lemma 4. *Let either $p \in (1, 2)$ or $q \in (1, 2)$, $q \geq p$. Then, for $r \in \{p, q\}$ there holds*

$$\left| |a + b|^{r-2}(a + b) - |a|^{r-2}a \right| \leq (3^{q-1} + 2^{q-1})|b|^{r-1}.$$

Proof. One can basically follow the proof of Lemma 3 in [26], by observing that $q \geq p$ plainly yields $3^{p-1} + 2^{p-1} < 3^{q-1} + 2^{q-1}$. \square

Important consequences of Lemma 2 are the following results for C^2 -regular functions.

Lemma 5. *Let $\varphi \in C^2(\mathbb{R}^n)$. If $p \geq 2$. Then, there holds*

$$\begin{aligned} & |\varphi(x) - \varphi(x + y)|^{p-2}(\varphi(x) - \varphi(x + y)) + |\varphi(x) - \varphi(x - y)|^{p-2}(\varphi(x) - \varphi(x - y)) \\ (5.16) \quad & \leq c|y|^p \quad \text{for all } x, y \in \mathbb{R}^n, \end{aligned}$$

with $c \equiv c(n, p, \|\varphi\|_{C^2})$.

Let $1 < p < 2$. Then, there holds

$$\begin{aligned} & |\varphi(x) - \varphi(x + y)|^{p-2}(\varphi(x) - \varphi(x + y)) + |\varphi(x) - \varphi(x - y)|^{p-2}(\varphi(x) - \varphi(x - y)) \\ (5.17) \quad & \leq c|y|^{p-1} \quad \text{for all } x, y \in \mathbb{R}^n, \end{aligned}$$

for $c = c(n, p, \|\varphi\|_{C^1})$.

Moreover, if $a(\cdot, \cdot)$ satisfies (2.6), then for every $q > 1$ we have

$$(5.18) \quad \begin{aligned} & a(x, y)|\varphi(x) - \varphi(x + y)|^{q-2}(\varphi(x) - \varphi(x + y)) \\ & \quad + a(x, -y)|\varphi(x) - \varphi(x - y)|^{q-2}(\varphi(x) - \varphi(x - y)) \\ & \leq c|y|^{q-1}, \end{aligned}$$

where $c = c(n, q, \|a\|_{L^\infty}, \|\varphi\|_{C^1})$.

If a belongs to $C^{0,\alpha}(\mathbb{R}^n \times \mathbb{R}^n)$ for some $\alpha \in (0, 1]$ and $q \geq 2$, then

$$(5.19) \quad \begin{aligned} & a(x, y)|\varphi(x) - \varphi(x + y)|^{q-2}(\varphi(x) - \varphi(x + y)) \\ & \quad + a(x, -y)|\varphi(x) - \varphi(x - y)|^{q-2}(\varphi(x) - \varphi(x - y)) \\ & \leq c(|y|^q + |y|^{q-1+\alpha}), \end{aligned}$$

with $c = c(n, q, \|a\|_{L^\infty}, [a]_{C^{0,\alpha}}, \|\varphi\|_{C^2})$.

Finally, if $a(x, y) = a(x, -y)$ for all $x, y \in \mathbb{R}^n$ and $q \geq 2$, then

$$(5.20) \quad \begin{aligned} & a(x, y)|\varphi(x) - \varphi(x + y)|^{q-2}(\varphi(x) - \varphi(x + y)) \\ & \quad + a(x, -y)|\varphi(x) - \varphi(x - y)|^{q-2}(\varphi(x) - \varphi(x - y)) \\ & \leq c|y|^q, \end{aligned}$$

holds true for $c = c(n, q, \|a\|_{L^\infty}, \|\varphi\|_{C^2})$.

Proof. Set

$$\begin{aligned} A & := -(\varphi(x) - \varphi(x + y)), \\ B & := (\varphi(x) - \varphi(x + y)) + (\varphi(x) - \varphi(x - y)). \end{aligned}$$

In these terms, we can apply Lemma 2 to get

$$\begin{aligned} & |\varphi(x) - \varphi(x + y)|^{p-2}(\varphi(x) - \varphi(x + y)) + |\varphi(x) - \varphi(x - y)|^{p-2}(\varphi(x) - \varphi(x - y)) \\ & = |A + B|^{p-2}(A + B) - |A|^{p-2}A \\ & \leq (p - 1)|B|(|A| + |B|)^{p-1} \\ & \leq c|y|^p, \end{aligned}$$

for all $x, y \in \mathbb{R}^n$. Here $c = c(n, p, \|\varphi\|_{C^2})$, which is (5.16). For (5.17), we only need Lagrange's Theorem to obtain

$$\begin{aligned} & |\varphi(x) - \varphi(x + y)|^{p-2}(\varphi(x) - \varphi(x + y)) + |\varphi(x) - \varphi(x - y)|^{p-2}(\varphi(x) - \varphi(x - y)) \\ & \leq c|y|^{p-1}, \end{aligned}$$

with $c = c(n, p, \|\varphi\|_{C^1})$. On the other hand, due to the presence of $a(\cdot, \cdot)$, which is a priori only bounded, we cannot apply the same procedure to the q -part of our operator, therefore, under (2.6) we can only invoke Lagrange's Theorem again to get

$$\begin{aligned} & a(x, y)|\varphi(x) - \varphi(x + y)|^{q-2}(\varphi(x) - \varphi(x + y)) \\ & \quad + a(x, -y)|\varphi(x) - \varphi(x - y)|^{q-2}(\varphi(x) - \varphi(x - y)) \\ & \leq c|y|^{q-1} \quad \text{for all } x, y \in \mathbb{R}^n, \end{aligned}$$

with $c = c(n, q, \|a\|_{L^\infty}, \|\varphi\|_{C^1})$. Nonetheless, if we assume extra regularity for $a(\cdot, \cdot)$, we can exploit again Lemma 2 to obtain

$$\begin{aligned} & a(x, y)|\varphi(x) - \varphi(x + y)|^{q-2}(\varphi(x) - \varphi(x + y)) \\ & \quad + a(x, -y)|\varphi(x) - \varphi(x - y)|^{q-2}(\varphi(x) - \varphi(x - y)) \\ & \quad \pm a(x, y)|\varphi(x) - \varphi(x - y)|^{q-2}(\varphi(x) - \varphi(x - y)) \\ & \leq a(x, y) \left(|A + B|^{q-2}(A + B) - |A|^{q-2}B \right) \\ & \quad + 2[a]_{C^{0,\alpha}}|y|^\alpha|\varphi(x) - \varphi(x - y)|^{q-1} \leq c(|y|^q + |y|^{q-1+\alpha}), \end{aligned}$$

where $c = c(n, q, \|a\|_{L^\infty}, [a]_{C^{0,\alpha}}, \|\varphi\|_{C^2})$. Notice that, when $|y| \leq 1$, the last term in (5.19) can be bounded by $c|y|^{q-1+\alpha}$.

Finally, we conclude the proof by stressing that the procedure employed to obtain (5.16) can be repeated verbatim when $q \geq 2$ provided that $a(x, y) = a(x, -y)$ for all $x, y \in \mathbb{R}^n$. In such a case, $a(\cdot, \cdot) \geq 0$ does reduce to a multiplicative factor allowing again the application of Lemma 2; we have

$$\begin{aligned} & a(x, y)|\varphi(x) - \varphi(x + y)|^{q-2}(\varphi(x) - \varphi(x + y)) \\ & \quad + a(x, -y)|\varphi(x) - \varphi(x - y)|^{q-2}(\varphi(x) - \varphi(x - y)) \\ & = a(x, y) \left(|\varphi(x) - \varphi(x + y)|^{q-2}(\varphi(x) - \varphi(x + y)) \right. \\ & \quad \left. + |\varphi(x) - \varphi(x - y)|^{q-2}(\varphi(x) - \varphi(x - y)) \right) \leq c|y|^q, \end{aligned}$$

with $c = c(n, q, \|a\|_\infty, \|\varphi\|_{C^2})$, which is (5.20). \square

Lemma 6. *Let $B_\varrho \subset \mathbb{R}^n$ be any ball centered in the origin with radius $\varrho \leq 1$ and $\varphi \in C^2(\mathbb{R}^n)$. Then, if $p \geq 2$ we have*

$$(5.21) \quad \int_{B_\varrho} \left| |\varphi(x) - \varphi(x + y)|^{p-2}(\varphi(x) - \varphi(x + y)) \right. \\ \left. + |\varphi(x) - \varphi(x - y)|^{p-2}(\varphi(x) - \varphi(x - y)) \right| K_{sp}(x, y) \, dy \leq c < \infty,$$

for $c = c(n, \Lambda, p, \|\varphi\|_{C^2(\mathbb{R}^n)})$. If $1/(1-s) < p < 2$, there holds

$$(5.22) \quad \int_{B_\varrho} \left| |\varphi(x) - \varphi(x + y)|^{p-2}(\varphi(x) - \varphi(x + y)) \right. \\ \left. + |\varphi(x) - \varphi(x - y)|^{p-2}(\varphi(x) - \varphi(x - y)) \right| K_{sp}(x, y) \, dy \leq c < \infty,$$

with $c = c(n, \Lambda, p, \|\varphi\|_{C^1(\mathbb{R}^n)})$. Moreover, under assumption (2.6) we have

$$(5.23) \quad \int_{B_\varrho} \left| a(x, y)|\varphi(x) - \varphi(x + y)|^{q-2}(\varphi(x) - \varphi(x + y)) \right. \\ \left. + a(x, -y)|\varphi(x) - \varphi(x - y)|^{q-2}(\varphi(x) - \varphi(x - y)) \right| K_{tq}(x, y) \, dy \leq c < \infty,$$

for $c = c(n, \Lambda, q, \|a\|_{L^\infty}, \|\varphi\|_{C^1})$.

If $a \in C^{0,\alpha}(\mathbb{R}^n \times \mathbb{R}^n)$ for some $\alpha \in (0, 1]$ and $q \geq \max \left\{ 2, (1-\alpha)(1-t) \right\}$, we have

$$\int_{B_\varrho} \left| a(x, y)|\varphi(x) - \varphi(x + y)|^{q-2}(\varphi(x) - \varphi(x + y)) \right.$$

$$(5.24) \quad +a(x, -y)|\varphi(x) - \varphi(x - y)|^{q-2}(\varphi(x) - \varphi(x - y)) \Big| K_{tq}(x, y) \, dy \leq c < \infty,$$

is satisfied. Here $c = c(n, \Lambda, q, \|a\|_{L^\infty}, [a]_{C^{0,\alpha}}, \|\varphi\|_{C^2})$.

Finally, if $a \in L^\infty(\mathbb{R}^n \times \mathbb{R}^n)$ symmetric in the sense that $a(x, y) = a(x, -y)$ for all $x, y \in \mathbb{R}^n \times \mathbb{R}^n$, and $q \geq 2$, then

$$(5.25) \quad \int_{B_\varrho} \left| a(x, y)|\varphi(x) - \varphi(x + y)|^{q-2}(\varphi(x) - \varphi(x + y)) \right. \\ \left. + a(x, -y)|\varphi(x) - \varphi(x - y)|^{q-2}(\varphi(x) - \varphi(x - y)) \right| K_{tq}(x, y) \, dy \leq c < \infty$$

holds true with $c = c(n, \Lambda, q, \|a\|_\infty, \|\varphi\|_{C^2})$.

Proof. Let $B_\varrho \subset \mathbb{R}^n$ be any ball centered in the origin with radius $\varrho \leq 1$. If $p \geq 2$, recalling (2.3) and (5.16),

$$\int_{B_\varrho} \left| |\varphi(x) - \varphi(x + y)|^{p-2}(\varphi(x) - \varphi(x + y)) \right. \\ \left. + |\varphi(x) - \varphi(x - y)|^{p-2}(\varphi(x) - \varphi(x - y)) \right| K_{sp}(x, y) \, dy \\ \leq c \int_{B_\varrho} |y|^{p-n-sp} \, dy < c < \infty,$$

where $c = c(n, \Lambda, p, \|\varphi\|_{C^2(\mathbb{R}^n)})$. If $p < 2$, by (5.17) and (2.4)₁ we have

$$\int_{B_\varrho} \left| |\varphi(x) - \varphi(x + y)|^{p-2}(\varphi(x) - \varphi(x + y)) \right. \\ \left. + |\varphi(x) - \varphi(x - y)|^{p-2}(\varphi(x) - \varphi(x - y)) \right| K_{sp}(x, y) \, dy \\ \leq c \int_{B_\varrho} |y|^{p-1-n-sp} \, dy < c < \infty,$$

with $c = c(n, \Lambda, p, \|\varphi\|_{C^1})$. Furthermore, if we assume (2.6), by (2.4)₂, (2.3) and (5.18) it follows that

$$\int_{B_\varrho} \left| a(x, y)|\varphi(x) - \varphi(x + y)|^{q-2}(\varphi(x) - \varphi(x + y)) \right. \\ \left. + a(x, -y)|\varphi(x) - \varphi(x - y)|^{q-2}(\varphi(x) - \varphi(x - y)) \right| K_{tq}(x, y) \, dy \\ \leq c \int_{B_\varrho} |y|^{q-1-n-tq} \, dy \leq c,$$

for $c = c(n, \Lambda, q, \|a\|_{L^\infty}, \|\varphi\|_{C^1})$. Clearly, in this case it does not matter if $q < 2$ or $q \geq 2$.

Finally, if $q \geq 2$ and in addition a belongs to $C^{0,\alpha}(\mathbb{R}^n \times \mathbb{R}^n)$, from (5.19) we get

$$\int_{B_\varrho} \left| a(x, y)|\varphi(x) - \varphi(x + y)|^{q-2}(\varphi(x) - \varphi(x + y)) \right. \\ \left. + a(x, -y)|\varphi(x) - \varphi(x - y)|^{q-2}(\varphi(x) - \varphi(x - y)) \right| K_{tq}(x, y) \, dy \\ \leq c \int_{B_\varrho} |y|^{q-1+\alpha} \, dy \leq c,$$

provided that also $q > (1 - \alpha)(1 - t)$. Here, $c = c(n, \Lambda, q, \|a\|_{L^\infty}, [a]_{C^{0,\alpha}}, \|\varphi\|_{C^2})$.

Finally, concerning the estimate in (5.25), by recalling (5.20) and (2.3), we can conclude that

$$\begin{aligned} & \int_{B_\varrho} \left| a(x, y) |\varphi(x) - \varphi(x + y)|^{q-2} (\varphi(x) - \varphi(x + y)) \right. \\ & \quad \left. + a(x, -y) |\varphi(x) - \varphi(x - y)|^{q-2} (\varphi(x) - \varphi(x - y)) \right| K_{tq}(x, y) \, dy \\ & \leq c \int_{B_\varrho} |y|^q \, dy \leq c, \end{aligned}$$

for $c = c(n, \Lambda, q, \|a\|_\infty, \|\varphi\|_{C^2})$. □
