

# ON CONVERGENCE OF A FAMILY OF RANDOM WALKS IN THE INFINITE DIMENSIONAL STIEFEL MANIFOLD

ANDREA C. G. MENNUCCI

*In memory of Prof. Giuseppe Da Prato.*

**ABSTRACT.** In this paper, we study random walks taking values in an infinite-dimensional space — either a Hilbert space, or an infinite-dimensional manifold embedded in it, such as the Stiefel manifold.

These random walks arise in problems in Shape Theory, particularly when stochastic optimization is applied. In these contexts, the random walks are defined at discrete times  $t \in \tau = \{t_0 = 0 < t_1 < t_2 < \dots\}$ . By suitably interpolating the paths between times  $t_i$  and  $t_{i+1}$ , we can view them as time-continuous random walks (for  $t \geq 0$ ).

A natural question arises: as the fineness of the partition  $\tau$  tends to zero, does such a family of random walks converge to a stochastic process? This paper provides some preliminary results in this direction, showing that — under appropriate conditions — weak convergence holds, in the sense of Prokhorov’s theorem.

## 1. INTRODUCTION

**1.1. Shape Theory, Curves.** “Shapes” appear in two broad categories of applications:

- *shape optimization*, where we want to find the best shape according to a criterion;
- *shape analysis*, where we study families of shapes for purposes of statistics, (automatic) cataloging, probabilistic modeling, etc.

Shape theory is central in computer vision because shapes partially characterize objects in images. We focus on the specific case where *shapes* are represented by smoothly immersed planar curves; this is a widely studied subject, see [Mennucci, 2013, Osher and Burger, 2013] and references therein. In this case, it should be noted that the *shape space* classically used in shape optimization is more precisely identified as *the space of embedded curves, up to a choice of parameterization*, whereas in shape analysis the space is usually identified as *the space of embedded*

*Key words and phrases.* infinite dimensional manifold, Riemannian manifold, Stiefel manifold, Hilbert space, tight family, random walk, Wiener process, Donsker’s Theorem, Brownian motion, stochastic completeness,

An earlier draft of this work was posted on the preprint server CVGMT at the author’s webpage (<https://cvgmt.sns.it/person/109/>). Because the present version is a thorough revision, that preprint has been removed.

FIGURE 1. *Stochastic minimization of curve-based segmentation energy, from [Dejala, 2010]. In the left pane, three curves: the blue curve is the best result so far; in green and red, stochastic steps. In the center pane, the current examined region for segmentation. In the right pane, the image to be segmented, with curves superimposed.*

curves, up to rotation, translation, scaling and reparameterization. We will not address this issue in this paper.

There are various reasons why it is useful to model the space of curves as a Riemannian manifold.

- In the past methods for *shape optimization* were devised that would find the solution by using appropriate *gradient flows*. Calling the minimizing flows *gradient flows*, however, implies a certain Riemannian metric on the space of curves.
- Modeling the space of curves as a Riemannian manifold also has obvious benefits in shape analysis: indeed the distance between curves can be used for clustering, the geodesic can be used to define the average of two shapes, and so on.

We concentrate on two models of “Riemannian manifolds of curves”, where we disregard translation and scaling.

- A model for open immersed curves  $c : [0, 1] \rightarrow \mathbb{R}^2$ ; using a transformation known as *square-root velocity representation* the Riemannian manifold is isometric to a subset of the unit sphere in  $V = L^2([0, 1])$ ; see [Srivastava et al., 2011].
- A model for closed immersed curves  $c : S^1 \rightarrow \mathbb{R}^2$ ; using an appropriate transformation the Riemannian manifold is isometric to a subset of the Stiefel manifold  $\mathbf{St}(2, V)$  (as defined in Sec.2.2); see [Younes et al., 2008, Younes, 1998, Sundaramoorthi et al., 2011].

Since the sphere in the first model is the special case  $\mathbf{St}(1, V)$ , we are in both cases interested in infinite dimensional Stiefel manifolds. In both cases, the space of smooth immersions is completed to a larger space of absolutely continuous curves, so that the “*shape space*” is now  $\mathbf{St}(p, V)$ .

Since stochastic methods play an important role in applications, we are then led to investigate them in  $\mathbf{St}(p, V)$ . In particular, in [Deiala, 2010] a stochastic minimization method was developed to seek numerically global minima for a task of image segmentation; curves would stochastically evolve by a scheme resembling the “random walk on manifold” presented later in Section 6; a pruning method (inspired by simulated annealing) would drive the random walk towards a global minimum: see Figure 1 on the facing page. In [Sundaramoorthi et al., 2011] a stochastic method was developed in  $\mathbf{St}(2, V)$ , similar to the classical Kalman filtering, to track a moving object.

A question remained open: could the numerical methods in [Deiala, 2010] and in [Sundaramoorthi et al., 2011] be explained as a space-time discretization of a yet-to-be-understood infinite-dimensional stochastic method in  $\mathbf{St}(2, V)$ ? Space discretization would not pose a problem, since it can be argued that  $\mathbf{St}(p, V)$  can be approximated by  $\mathbf{St}(p, \mathbb{R}^N)$  for  $N$  large (using *e.g.* Fourier series). This leaves the following question: does a discrete time random walk in  $\mathbf{St}(p, V)$  somehow approximate a time continuous stochastic process in  $\mathbf{St}(p, V)$ ? More generally: how can we define probabilities and stochastic methods in  $\mathbf{St}(p, V)$ ? Some positive and negative results were found in [Bardelli and Mennucci, 2017]. In this paper we will eventually provide a positive result in Theorem 7.12: the discrete time random walk on  $\mathbf{St}(p, V)$  can indeed converge to a time continuous process, when the time partition gets finer and finer. In the spirit of Donsker’s theorem, this is a first step to an operative definition of “Brownian Motion” on  $\mathbf{St}(p, V)$ . Accordingly, in the present paper we focus on tightness and on the existence of limit points. All of the above will eventually provide a sound foundation for methods such as the ones in [Deiala, 2010] and in [Sundaramoorthi et al., 2011].

**1.2. Main Results.** The main results of this paper may be summarized as follows. First, in the abstract Hilbert setting we prove a tightness criterion for interpolated random walks in  $C(I; H)$ , based on a compact operator  $K$ , a first-order approximation of the increments, and suitable growth estimates; this is Theorem 5.14, and it yields narrow limit points in  $C(\mathbb{R}^+; H)$ . Second, we show that the same criterion applies to geodesic random walks on manifolds embedded in  $H$ , provided the embedding and the exponential map satisfy natural geometric bounds; this is Theorem 6.8. Third, we verify those hypotheses for infinite-dimensional Stiefel manifolds  $\mathbf{St}(p, V)$ , obtaining tightness for the corresponding geodesic random walks and an invariance property under the right action of  $O(p)$ ; see Theorem 7.12 and the subsequent Corollary. What we do not prove here is uniqueness of the limit, an intrinsic characterization of the limit points, or an identification of the limit with a specific stochastic differential equation; these questions are left for future work.

**1.3. Layout of the paper.** Let  $(\Omega, \mathcal{F}, \mathbb{P})$  be a probability space. Let  $H$  be a separable Hilbert space,  $M$  a manifold embedded in  $H$ , possibly infinite dimensional. Let  $S = H$  or  $S = M$ .

Let  $\mathfrak{T}$  be a family whose elements  $\tau$  are discrete countable sets of positive rational numbers (a precise definition will be in Definition 3.23).

We now describe the organization of the paper and fix the notation for the random walks and the associated interpolated processes.

In this paper we study processes  $\mathfrak{X}^\tau$  which are random functions with values in the Frechét space  $C(\mathbb{R}^+; S)$ , where  $\mathbb{R}^+ = [0, \infty)$ . We denote by  $\mathfrak{X}_t^\tau : \Omega \rightarrow$

$S$  the random variable obtained from the process  $\mathfrak{X}^\tau$  at time  $t$ , so that  $\mathfrak{X}^\tau = (\mathfrak{X}_t^\tau)_{t \in \mathbb{R}^+}$ . Each process  $\mathfrak{X}^\tau$  is obtained by interpolating a random walk  $X^\tau = (X_n^\tau)_{n \in \mathbb{N}}$ , observed at discrete times  $t \in \tau = \{t_0 = 0 < t_1 < t_2 \dots\}$ . More precisely, for  $t \in [t_n, t_{n+1}]$ , the value  $\mathfrak{X}_t^\tau$  is obtained by interpolating between  $X_n^\tau$  and  $X_{n+1}^\tau$ .

Section 5 develops an abstract tightness criterion for processes  $\mathfrak{X}^\tau$  taking values in a separable Hilbert space  $S = H$ . Section 6 applies it to geodesic random walks on manifolds  $S = M$  embedded in  $H$ . Section 7 treats infinite-dimensional Stiefel manifolds and derives the corresponding tightness result. Appendix A contains some useful lemmas, and Appendix B contains deferred proofs.

We will use some definition and results from Probability Theory; since there may be ambiguity in some definitions, and some results are not easily found in the needed generality, we have written a compendium in [Mennucci].

**1.4. Random Walk and Interpolation.** Here we briefly define the discrete-time random walks  $X^\tau = (X_n^\tau)_{n \in \mathbb{N}}$  and the associated interpolated processes  $\mathfrak{X}^\tau = (\mathfrak{X}_t^\tau)_{t \in \mathbb{R}^+}$  that we will study (more details will be in Section 3.4).

Let  $\mathbb{R}^+ = [0, \infty)$ ; let  $H, U$  be separable Hilbert spaces. Let

$$\tau = \{t_0 = 0 < t_1 < t_2 \dots\} \subset \mathbb{Q} \quad . \quad (1.1)$$

Note again that these times are assumed to be rational numbers, for convenience (See Lemma 3.34). We will need a source of random noise: for  $t \in \mathbb{R}^+$ , a family of i.i.d. r.v.  $Y_t$  taking values in  $U$ , each with law  $\gamma$ . We will need a Borel map

$$D = D(x, v, t, s) : H \times U \times (\mathbb{R}^+)^2 \rightarrow H \quad (1.2)$$

continuous in  $s$  and such that  $D(x, v, t, 0) = 0$ . We fix  $X_0^\tau = \mathfrak{X}_0$  a random variable, and we define recursively

$$X_{n+1}^\tau = X_n^\tau + D(X_n^\tau, Y_{t_n}, t_n, (t_{n+1} - t_n)) \quad . \quad (1.3)$$

Then we interpolate using

$$\mathfrak{X}_t^\tau = X_n^\tau + D(X_n^\tau, Y_{t_n}, t_n, (t - t_n)) \quad (1.4)$$

for  $t_n \leq t \leq t_{n+1}$ ; so each trajectory  $t \mapsto \mathfrak{X}_t^\tau(\omega, t)$  is continuous; hence each  $\mathfrak{X}^\tau$  is a r.v. taking value in  $C(\mathbb{R}^+; H)$ , the Frechét space of continuous functions  $x : \mathbb{R}^+ \rightarrow H$ .

Since  $U$  is used only in the second argument of  $D$ , and  $H, U$  are isomorphic, we can decide that  $H = U$  with no loss of generality.

## 2. MOTIVATION

**2.1. Finite Dimensional Manifolds.** The theory of Stochastic Differential Equations in finite dimensional Riemannian manifolds  $M$  is well developed; see *e.g.* [Hsu, 2002]. In particular, there are multiple equivalent definitions of *Brownian Motion*; each based on different principles,

- stochastic differential equations in local charts,
- development of Euclidean Brownian Motion (Example 2.6.8 in [Hsu, 2002]),
- the heat equation and its transition probabilities,
- limit of geodesic random walks <sup>1</sup>;

but all leading to the same ultimate definition: see Proposition 3.2.1 in [Hsu, 2002].

We define this concept as in Section 4.2 in [Hsu, 2002].

---

<sup>1</sup>Properly defined in Sec. 3.5.1.

**Definition 2.1** (Stochastic completeness). *Consider a non-compact connected manifold  $M$ , and let  $\infty$  be the point added by the Alexandroff compactification (the one-point topological compactification). For any continuous path  $x : \mathbb{R}^+ \rightarrow M \cup \{\infty\}$  let*

$$e = e(x) = \sup\{t \geq 0 : \forall s, 0 \leq s < t, x(s) \in M\} \quad (2.2)$$

*be the first time  $t$  such that  $x(t) = \infty$ ; we agree that  $x(s) = \infty$  for  $s \geq e$ . Suppose that  $\mathfrak{X} = (\mathfrak{X}_t)_{t \in \mathbb{R}^+}$  is Brownian Motion, whose paths are continuous in  $M \cup \{\infty\}$ . A manifold is called stochastically complete if  $e(\mathfrak{X}_\cdot)$  is infinite almost surely:*

$$\mathbb{P}\{e(\mathfrak{X}_\cdot) = \infty\} = 1 \quad . \quad (2.3)$$

A thorough discussion of this problematic may be found in [Grigor'yan, 1999]. There is an important problem: even if the manifold is complete, it may fail to be *stochastically complete*. ([Grigor'yan, 1999] attributes the first such example to [Azencott, 1974]).

There are many properties of  $M$  that ensure that the manifold is *stochastically complete*, such as as: volume growth of geodesic balls, isoperimetric inequalities, conservation of mass in the heat equation, curvature bounds, etc.; see [Grigor'yan, 1999]. (Indeed our Theorem 6.8 requires a kind of curvature bound).

**2.1.1. Infinite Dimensional Manifolds.** When the Riemannian manifold  $M$  is infinite dimensional, though, we immediately identify some obstacles.

- When the manifold  $M$  has dimension  $N$ , we have an important property: each tangent space  $T_x M$  is isomorphic to  $\mathbb{R}^N$ ; hence there is a canonical choice of Gaussian measure  $N(0, \mathbb{I})$  on each one. This is, in a sense, the “white noise” that is driving the Brownian Motion.

When the manifold  $M$  is modeled on a infinite dimensional Hilbert space  $H$  then there is no Gaussian measure in  $H$  that is rotationally invariant (actually, rotations of a Gaussian measure  $N(0, Q)$  tend to be mutually singular, as explained in [Bogachev, 1998]). So we will need to decide what “white noise” we will use.

- While the *heat equation* can be defined in  $H$ , an approach using this tool would have to deal with some technical difficulties; for example, the heat equation is not *Feller*, that is, it does not regularizes the initial data.

Moreover, usually the transition probabilities of the heat kernel are used; these transition probabilities are expressed as densities with respect to the volume form; but an infinite dimensional Riemannian manifold does not have a volume form that may be used as a reference measure.

- The Hopf–Rinow theorem is false, closed bounded sets are not necessarily compact.
- The one point compactification is not useful, since any non-empty open set contains a sequence such that  $x_n \rightarrow \infty$
- The radial process is not useful, since there may be examples of complete Riemannian manifolds where the trajectories of the Brownian Motion are bounded, but each of them would have  $\mathfrak{X}_t \rightarrow \infty$  in finite time. (A key point to build such an example may be [Bessaga, 1966]).

Prokhorov’s theorem, on the other end, is valid in any separable metric space (regardless of “dimension”): so an appropriate concept of *tightness* will be the key element for Theorem 6.8.

For all the reasons above, it may be quite difficult to refer to pre-existing studies and results of Brownian motions on finite-dimensional manifolds, when addressing the problem here presented.

**2.2. Stiefel Manifolds.** The results in this paper will be valid when  $M$  is a Stiefel manifold.

Let  $n, p$  be natural numbers with  $1 \leq p \leq n$ ; classically, the Stiefel manifold  $\mathbf{St}(p, \mathbb{R}^n)$  is defined as the set of all frames composed of  $p$  orthonormal vectors in  $\mathbb{R}^n$ ; those frames are represented as  $n \times p$  matrices. Geodesics in Stiefel manifolds  $\mathbf{St}(p, \mathbb{R}^n)$  are known to have closed form solutions as demonstrated by Edelman et al. [Edelman et al., 1998] in Section 2.2.2.<sup>2</sup> This property extends to infinite dimensional manifolds, as will be explained in Section 7.3.1.

Let again  $p \geq 1$  be a natural number, and let  $V$  be a Hilbert space with  $\dim(V) \geq 2p$  (possibly infinite dimensional). Let  $H = V^p$ , we write

$$x \in H \quad , \quad x = (x_1, \dots, x_p) \quad (2.4)$$

and

$$\|x\|_H = \sqrt{\sum_{i=1}^p \|x_i\|_V^2} \quad (2.5)$$

as usual (and similarly for scalar products). By analogy to the finite dimensional space, we will call *columns* the  $p$  vectors  $x_i$  that compose  $x$ . We define

$$\pi_i : H \rightarrow V \quad , \quad \pi_i(x) = x_i \quad . \quad (2.6)$$

**Definition 2.7.** We define  $\mathbf{St}(p, V)$  as the manifold of  $x \in H$  such that

$$\langle x_i, x_j \rangle_V = \delta_{i,j} \quad (2.8)$$

and  $\mathbf{St}(p, V)$  is an embedded manifold in  $H$  of codimension  $p(p+1)/2$ .

The sphere is the special case  $\mathbf{St}(1, V)$ . The geometry of Stiefel manifolds is pretty well understood [Edelman et al., 1998, Harms and Mennucci, 2012]. See Section 7.3.1 for details.

### 3. DEFINITIONS

Let  $H$  be a separable Hilbert space. We agree that variables  $n, m, h, k, i, j, l$  are natural numbers. We will use the theory of “*nets*”; in this paper a net is a function whose domain is a partially ordered directed set with no maxima (abbreviated to “*dposet*” in the following: see [Mennucci] for details and properties).

#### 3.1. Measures.

**Definition 3.1.** Given measurable spaces  $(X_1, \Sigma_1)$  and  $(X_2, \Sigma_2)$ , a measurable mapping  $f : X_1 \rightarrow X_2$  and a measure  $\mu : \Sigma_1 \rightarrow [0, +\infty]$ , the **push forward** of  $\mu$  is defined to be the measure  $f_{\#}\mu : \Sigma_2 \rightarrow [0, +\infty]$  given by

$$f_{\#}\mu(B) = \mu(f^{-1}(B)) \quad \text{for all } B \in \Sigma_2 \quad . \quad (3.2)$$

The push forward measure is denoted also as  $f_*\mu$ ,  $\mu \circ f^{-1}$ , or  $f\#\mu$ .

<sup>2</sup>[Edelman et al., 1998] credits a personal communication by R. Lippert for the final closed form formula (7.17).

**Definition 3.3** (Law *a.k.a.* Distribution). If  $(\Omega, \mathcal{F}, \mathbb{P})$  is a probability space and  $Y : \Omega \rightarrow X_2$  is a r.v. and  $\gamma$  is a probability measure on  $(X_2, \Sigma_2)$ , we will write

$$Y \sim \gamma \quad \text{when} \quad \gamma = Y_{\#} \mathbb{P} \quad , \quad (3.4)$$

we will say that  $\gamma$  is the *law* or the *distribution* of  $Y$ ; similarly for  $Y, Z : \Omega \rightarrow X_2$

$$Y \sim Z \quad \text{when} \quad Y_{\#} \mathbb{P} = Z_{\#} \mathbb{P} \quad . \quad (3.5)$$

We will use the *narrow convergence*.<sup>3</sup>

**Definition 3.6** (Narrow Convergence). Let  $S$  be a Hausdorff topological space. Given a net of Radon measures  $\mu_\alpha, \mu$  on  $S$ , for  $\alpha \in A$  a *dposet*, we will say that  $\mu_\alpha \rightarrow \mu$  **narrowly** if

$$\forall f \in C_b(S) \quad , \quad \lim_{\alpha} \int_S f(x) d\mu_\alpha(x) = \int_S f(x) d\mu(x) \quad . \quad (3.7)$$

We agree on this (non standard) definition.

**Definition 3.8.** Let  $\mathfrak{T}$  be a dposet, and  $S$  be a Hausdorff topological space. Let  $\mu_\tau$  be a net of Radon measures on  $S$ : it is **tight** if  $\forall \varepsilon > 0$  there is a compact set  $C \subseteq S$  such that

$$\limsup_{\tau \in \mathfrak{T}} \mu_\tau(S \setminus C) \leq \varepsilon \quad . \quad (3.9)$$

Let  $\mathfrak{X}^\tau$  be a net of r.v. taking values in  $S$ , for  $\tau \in \mathfrak{T}$ : it is **tight** if the net of laws  $\mu_\tau = \mathfrak{X}_{\#}^\tau \mathbb{P}$  is tight.

### 3.2. Probability setting.

**Hypotheses 3.10.** We fix a constant  $c_t > 0$ , that will be used to bound temporal finess, and a constant  $c_3 > 0$  that will be used to control exponential decay.<sup>4</sup>

We will use a Borel measure  $\gamma$  on  $H$  satisfying:

•

$$\int_H \|x\|^4 e^{4c_3 c_t \|x\|} d\gamma(x) < \infty \quad (3.11)$$

•  $\gamma$  is centered

$$\int_H x d\gamma(x) = 0 \quad ; \quad (3.12)$$

• There is<sup>5</sup> a linear compact symmetric injective operator  $K : H \rightarrow H$  such that  $\gamma(K(H)) = 1$  and

•

$$\int_H \|K^{-1}x\|^4 d\gamma(x) < \infty \quad . \quad (3.13)$$

All the above hold true when  $\gamma = N(0, Q)$  a Gaussian measure (as defined in next section): see Proposition 3.15 and Remark 5.8.

Let  $\gamma$  be such a probability on  $H$ . We need a Probability Space, so that we have i.i.d. r.v.  $Y_t : \Omega \rightarrow H$  each with distribution  $Y_{t\#} \mathbb{P} = \gamma$ , for  $t \in \mathbb{Q}$ ; to this end we may set

$$\Omega = \times_{t \in \mathbb{Q}} H \quad , \quad \mathcal{F} \quad , \quad \mathbb{P} = \otimes_{t \in \mathbb{Q}} \gamma \quad ; \quad (3.14)$$

<sup>3</sup>Other text call this *convergence in distribution* or *weak convergence*.

<sup>4</sup>The constants  $c_3, c_t$  will appear again in subsequent hypotheses.

<sup>5</sup>The last two requests are loosely connected to what is explained in Example 3.8.13 in [Bogachev, 1998].

where  $\mathcal{F}$  is the  $\sigma$ -algebra generated by null sets of  $\mathbb{P}$  and by  $\mathcal{B}(\Omega)$ , the Borel  $\sigma$ -algebra.

**Proposition 3.15.** *For any  $c \in [0, 4c_3]$ ,  $\alpha \in [0, 4]$  there is a constant  $\tilde{c} = \tilde{c}(\alpha, c, c_t) > 0$  such that for all  $\delta \in [0, c_t]$ ,*

$$\mathbb{E}[g(\delta\|Y_t\|)] \leq \tilde{c}\delta^\alpha \quad , \quad (3.16)$$

where  $g(s) = s^\alpha e^{cs}$ . (The proof is in Section B.)

**3.3. Gaussian measures.** Let  $H$  be a separable Hilbert space.

**Definition 3.17.** Suppose that  $a \in H$  and  $Q : H \rightarrow H$  is a linear symmetric trace-class operator such that the quadratic form  $\langle x, Qx \rangle_H$  is non negative. We recall that  $\gamma = N(a, Q)$  is a Gaussian measure in the Hilbert space  $H$  when the characteristic function (or Fourier transform) is

$$\forall f \in H \quad , \quad \int_H e^{i\langle f, x \rangle} d\gamma(x) = \exp\left(i\langle a, f \rangle - \frac{1}{2}\langle x, Qx \rangle_H\right) \quad (3.18)$$

(Theorem 2.3.1 in [Bogachev, 1998]; Section 1.5 in [Da Prato, 2006].) The mean and variance are characterized by

$$\langle f, a \rangle = \int_H \langle f, x \rangle d\gamma(x) \quad (3.19)$$

$$\langle f, Qg \rangle_H = \int_H \langle f, x - a \rangle \langle g, x - a \rangle d\gamma(x) \quad (3.20)$$

for all  $f, g \in H$ . In particular  $\gamma$  is called *centered* when  $a = 0$  and *non-degenerate* when the variance has empty kernel.

The proposition 3.15 is true for Gaussian Measures.

**Proposition 3.21.** *Let  $c \geq 0, \alpha > 0$  and let  $g(s) = s^\alpha e^{cs}$ , suppose  $Y \sim N(0, Q)$  then there is a  $\tilde{c} = \tilde{c}(\alpha, c, Q, c_t) > 0$  such that for  $0 \leq \delta \leq c_t$*

$$\mathbb{E}[g(\delta\|Y\|)] \leq \tilde{c}\delta^\alpha \quad . \quad (3.22)$$

(The proof is in Section B.)

**3.4. Random walk.** As aforementioned, in this paper a **net** is a function whose domain is a partially ordered directed set with no maxima (abbreviated to “*dposet*”). We will use these dposets.

**Definition 3.23.** We fix a constant  $c_t > 0$ , the same constant as in Hypotheses 3.10.

(1) Let

$$\tau = \{t_0 = 0 < t_1 < t_2 \dots\} \subset \mathbb{Q} \quad (3.24)$$

be such that

$$\lim_{n \rightarrow \infty} t_n = \infty \quad , \quad \sup_n (t_{n+1} - t_n) \leq c_t \quad . \quad (3.25)$$

Let  $\mathfrak{T}$  be the dposet of all such  $\tau$ , ordered by inclusion.

(2) Let  $T > 0$  we define  $\mathfrak{T}_T$  be the dposet of all  $\tau$  of the form

$$\tau = \{t_0 = 0 < t_1 < t_2 < \dots < t_n = T\} \quad (3.26)$$

with  $t_0, t_1, \dots, t_{n-1} \in \mathbb{Q}$  and again  $\max_{1 \leq j \leq n} (t_j - t_{j-1}) \leq c_t$ . (Note that we do not require that  $T \in \mathbb{Q}$ .)

We will use  $\mathfrak{T}$  for processes with  $t \in \mathbb{R}^+ = [0, \infty)$ ; while we will use  $\mathfrak{T}_T$  for processes with  $t \in [0, T]$ . We will actually define all processes as in the first case, for simplicity; but then, up to restricting  $t \in [0, T]$ , we will study tightness using  $\tau \in \mathfrak{T}_T$ .

Let  $H$  be a separable Hilbert space.

**Definition 3.27.** We will need a Borel map

$$D : H^2 \times (\mathbb{R}^+)^2 \rightarrow H \quad (3.28)$$

continuous in the last argument and such that  $D(x, v, t, 0) = 0$ .

For each  $\tau$ , we define an interpolated process  $\mathfrak{X}^\tau = (\mathfrak{X}_t^\tau)_{t \geq 0}$  taking values in  $H$ .

We fix  $\mathfrak{X}_0$  a random variable taking values in  $H$ , independent of all  $Y_t$ .

To define  $\mathfrak{X}^\tau$  we define auxiliary random walks  $X_n^\tau$  for  $n \in \mathbb{N}$ ; where we define  $X_0^\tau = \mathfrak{X}_0$ , and we define recursively

$$X_{n+1}^\tau = X_n^\tau + D(X_n^\tau, Y_{t_n}, t_n, (t_{n+1} - t_n)) \quad (3.29)$$

then we interpolate using

$$\mathfrak{X}_t^\tau = X_n^\tau + D(X_n^\tau, Y_{t_n}, t_n, (t - t_n)) \quad (3.30)$$

for  $t_n \leq t \leq t_{n+1}$ ; so each trajectory  $t \mapsto \mathfrak{X}_t^\tau(\omega, t)$  is continuous; hence each  $\mathfrak{X}^\tau$  is a r.v. taking value in  $C(\mathbb{R}^+; H)$ , the Frechét space of continuous functions  $x : \mathbb{R}^+ \rightarrow H$  with  $\mathbb{R}^+ = [0, \infty)$ .

Note that, for all  $\tau$ , we have  $\mathfrak{X}_0 = \mathfrak{X}_0^\tau$ .

**Proposition 3.31** (Filtration). *Let  $\mathcal{F}_t$  be the  $\sigma$ -algebra generated by  $\mathfrak{X}_0$  and by  $Y_s$  for  $s < t$  (augmented with the null sets of  $\mathbb{P}$ .) The process  $X_n^\tau$  for  $t_n \leq t$  is  $\mathcal{F}_t$ -measurable. The process  $\mathfrak{X}_s^\tau$  for  $s \leq t$  is  $\mathcal{F}_t$ -measurable.*

*Remark 3.32.* The choice of interpolation (1.4) has a beneficial effect: suppose  $T$  is positive but  $T \notin \tau$ ; define  $\hat{\tau} = (\tau \cup \{T\}) \cap [0, T]$  so  $\hat{\tau} \in \mathfrak{T}_T$ , then

$$\mathfrak{X}_t^{\hat{\tau}} = \mathfrak{X}_t^\tau \quad \forall t \leq T \quad (3.33)$$

This means that, up to adding  $T$  to  $\tau$ , we can consider any process defined above as a process  $\mathfrak{X}_t^\tau$  for  $t \in [0, T]$  and  $\tau \in \mathfrak{T}_T$ . (Note that we do not require that  $T \in \mathbb{Q}$ .)

We recall that  $C(I; H)$  is a complete separable metric space; so when the topology associated to probability measures on  $C(I; H)$  is the narrow topology and the family is tight (as defined in Definition 3.8), by Prokhorov's theorem<sup>6</sup> the set of limit points is not empty. When  $I = [0, T]$  this can also be explained using sequences.

**Lemma 3.34.** *Let  $T > 0$ ,  $I = [0, T]$ ; let  $q_0 = 0, q_1 = T$  and*

$$\{q_2, q_3, \dots\} = (0, T) \cap \mathbb{Q} \quad (3.35)$$

*be an enumeration, let*

$$\theta_n = \{q_0, q_1, \dots, q_n\} \quad ; \quad (3.36)$$

*then, for  $n \geq 2$ , the sequence  $(\theta_n)_n$  is cofinal in  $\mathfrak{T}_T$ . So the limit points*

$$\bigcap_{\hat{\tau} \in \mathfrak{T}_T} \overline{\{\mathfrak{X}^\tau : \hat{\tau} \subseteq \tau\}} \quad (3.37)$$

---

<sup>6</sup>See the version of Prokhorov's theorem in [Mennucci].

along  $\mathfrak{T}_T$  coincide with the limit points

$$\bigcap_{n \in \mathbb{N}} \overline{\{\mathfrak{X}^{\theta_k} : k \geq n\}} \quad (3.38)$$

along the sequence  $(\theta_n)_n$ . Similarly limits, limsup, liminf, tightness, etc, can be defined using that sequence  $(\theta_n)_n$ .

A similar result does not hold for  $\mathfrak{T}$ .

**Proposition 3.39.** *There does not exist a cofinal sequence  $f : \mathbb{N} \rightarrow \mathfrak{T}$ . (The proof is in Appendix B).*

**3.5. Manifold.** Suppose  $M$  is a manifold smoothly embedded in  $H$ ; we consider it as a Riemannian manifold, since it inherits the scalar product from  $H$ . For  $x \in M, v \in T_x M$  we denote by  $\exp_x(v)$  the exponential map. We require that  $M$  be a closed subset, so it is geodetically complete. We consider  $T_x M$  as a linear subspace of  $H$ , not as its affine translation containing  $x$ . For  $x \in M$  we define the orthogonal projection  $\pi_{T_x M} : H \rightarrow T_x M$ ; note that  $\pi_{T_x M}$  is symmetric that is  $\pi_{T_x M} = \pi_{T_x M}^*$ ; we will call  $P_x = \pi_{T_x M}$  for simplicity.

**3.5.1. Geodesic random walks on manifolds.** In this case, for each  $\tau$ , we define an interpolated process  $\mathfrak{X}^\tau = (\mathfrak{X}_t^\tau)_{t \geq 0}$  taking values in  $M$ . We fix  $\mathfrak{X}_0$  a random variable taking values in  $M$ , independent of all  $Y_t$ . We define recursively  $X_0^\tau = \mathfrak{X}_0$  and

$$X_{n+1}^\tau = \exp_{X_n^\tau}(\sqrt{(t_{n+1} - t_n)} P_{X_n^\tau} Y_{t_n}) \quad (3.40)$$

Then again we define  $\mathfrak{X}^\tau$  by interpolating along geodesics

$$\mathfrak{X}_t^\tau = \exp_{X_n^\tau}(\sqrt{(t - t_n)} P_{X_n^\tau} Y_{t_n}) \quad (3.41)$$

for  $t_n \leq t \leq t_{n+1}$ ; and again  $t \mapsto \mathfrak{X}_t^\tau$  is continuous.

This kind of *random walk* will be called *geodesic random walk*.

If, for  $x \in M, y \in H$ , we let

$$D(x, y, t, s) \stackrel{\text{def}}{=} \exp_x(\sqrt{s} P_x y) - x \quad (3.42)$$

then we obtain the same definition as in the previous section 3.4; so all comments and results apply to this case as well. Note that, in the words of Section 2.1.1,  $P_x Y_t$  is the source of “white noise” that we are using to drive the random walk. We will come back to manifolds in Section 6 and to Stiefel manifolds in Section 7

#### 4. TIGHTNESS BY ASCOLI-ARZELÀ THEOREM

In the following, for  $\psi : \mathbb{R} \rightarrow \mathbb{R}$ , “monotonic” means *monotonically weakly increasing* that is  $s \leq t \Rightarrow \psi(s) \leq \psi(t)$ .

**Definition 4.1.** Let  $I \subseteq \mathbb{R}$  be an interval,  $E$  be a normed vector space with norm  $\|\cdot\|_E$ ; for  $x : I \rightarrow E$  uniformly continuous and  $\eta > 0$  we define *the modulus of continuity*

$$\omega_{I,E}(x, \eta) \stackrel{\text{def}}{=} \sup\{\|x(t) - x(s)\|_E : t, s \in I, |t - s| \leq \eta\} \quad ; \quad (4.2)$$

note that  $\omega_{I,E}(x, \cdot)$  is continuous, sub-additive, monotonic, and  $\omega_{I,E}(x, 0) = 0$ .

We recall that a set is called *pre-compact* if its closure is compact. We will use this version of Ascoli-Arzelà Theorem. (Recall that if  $I$  is compact then  $C(I; S) = C_b(I; S)$ )

**Theorem 4.3.** *Suppose  $H$  is a Banach space. Let  $I \subseteq \mathbb{R}$  be a compact interval. Let  $F \subseteq C(I; H)$  be a family of continuous functions  $x : I \rightarrow H$ . Consider these two clauses:*

- *there is  $J \subseteq I$  countable dense subset such that for each  $t \in J$  there exists a pre-compact set  $C_t \subset H$  such that  $\forall x \in F, x(t) \in C_t$  ;*
- 

$$\lim_{\eta \rightarrow 0} \sup_{x \in F} \omega_{I, H}(x, \eta) = 0 \quad . \quad (4.4)$$

*The above two clauses hold if and only if  $F$  is pre-compact in  $C(I; H)$ .*

This is a Banach-valued version of the classical Ascoli-Arzelà criterion. For the reader's convenience, the idea is as follows: one first uses clause (i) and a diagonal argument on the countable dense set  $J$  to extract a subsequence converging pointwise on  $J$ ; clause (ii) gives a uniform modulus of continuity, which extends the pointwise limit on  $J$  to a continuous limit on  $I$  and upgrades convergence on  $J$  to uniform convergence on all of  $I$ . The converse implication is immediate from pre-compactness in  $C(I; H)$ .

For probability theory we transform the above as follows.

**Theorem 4.5.** *Suppose  $H$  is a Banach space. Let  $I = [0, T]$ . Suppose that  $\mathfrak{X}^\alpha : \Omega \rightarrow C(I; H)$  is a net of processes (with  $\alpha \in A$ ) satisfying the following two clauses.*

- *$\forall \varepsilon > 0$ , there exist, a countable set  $J = \{a_0, a_1, \dots, a_j, \dots\}$  dense in  $I$ , and compact sets  $C_j \subset H$ , such that*

$$\forall \alpha \in A \quad \forall j \in \mathbb{N}, \quad \mathbb{P}\{\mathfrak{X}^\alpha(a_j) \notin C_j\} \leq \varepsilon 2^{-j} \quad . \quad (4.6)$$

- *$\forall \varepsilon_0 > 0, \forall \varepsilon_1 > 0, \exists \eta > 0, \exists \alpha_0 \in A$  such that*

$$\forall \alpha \in A, \alpha \geq \alpha_0 \Rightarrow \mathbb{P}\{\omega_{I, H}(\mathfrak{X}^\alpha, \eta) \geq \varepsilon_0\} \leq \varepsilon_1 \quad . \quad (4.7)$$

*Then the net  $\mathfrak{X}^\alpha$  is tight<sup>7</sup> in  $C(I; H)$ .*

This follows immediately from Theorem 4.3; for a more expanded version in the same setting, see Theorem 6.28 in [Mennucci].

**Remark 4.8.** The second hypothesis (4.7) may be reformulated as

$$\forall \varepsilon_0 > 0 \quad , \quad \lim_{\eta \rightarrow 0} \limsup_{\alpha} \mathbb{P}\{\omega_H(I, \mathfrak{X}^\alpha, \eta) \geq \varepsilon_0\} = 0 \quad (4.9)$$

since  $\omega$  is monotonic in  $\eta$ .

## 5. TIGHTNESS OF RANDOM WALKS

Let again  $H$  be a separable Hilbert space. The purpose of this section is to state and prove the Theorem 5.14 on tightness of random walks in  $H$ .

**5.1. Tightness operator.** Let  $\gamma$  be as defined in Hypotheses 3.10. We required in Hypotheses 3.10 that there is  $K : H \rightarrow H$  a linear symmetric compact injective operator such that  $\gamma(K(H)) = 1$ , equivalently

$$\mathbb{P}(Y_t \in K(H)) = 1 \quad \forall t \quad . \quad (5.1)$$

Define now

$$D^K(0, r) = \{Kx : x \in H, \|x\| \leq r\} = K(B_H(0, r)) = rK(B_H(0, 1)) \quad (5.2)$$

then

---

<sup>7</sup>See Definition 3.8.

- they are pre-compact (this means that the closures  $\overline{D^K(0, r)}$  are compact), and
- 

$$\bigcup_n D^K(0, n) = K(H) \quad (5.3)$$

so

$$\gamma\left(\bigcup_n D^K(0, n)\right) = 1 \quad ; \quad (5.4)$$

- this means that  $\forall \varepsilon > 0 \exists n$  such that

$$\gamma(D^K(0, n)) \geq 1 - \varepsilon \quad . \quad (5.5)$$

*Remark 5.6.* Since  $H$  is a separable Hilbert space, then every probability measure on it is Radon hence tight; the above gives us an accessible family of sets for tightness of  $\gamma$ .

Up to rescaling  $K$  we will assume that

$$\forall v \in H, \|Kv\|_H \leq \|v\|_H \quad . \quad (5.7)$$

*Remark 5.8.* In general, for any Hilbert space  $H$  and Gaussian measure  $\gamma = N(0, Q)$ , such operator  $K$  always exists.

*Remark 5.9.* The role of the compact operator  $K$  is to provide a compact scale on the Hilbert space  $H$ . In infinite dimension, bounded sets in the ambient norm  $\|\cdot\|_H$  are typically not compact, so moment bounds in  $H$  alone do not yield tightness. By contrast, if  $K$  is a compact operator, the sets  $D^K(0, r)$  are precompact in  $H$ ; equivalently, boundedness in the  $K$ -norm means confinement in a precompact subset of  $H$ . The first part of the proof of Theorem 5.14 uses  $K$  to obtain compact containment at fixed times, while the second part uses the ambient  $H$ -norm to control the modulus of continuity. Gaussian measures naturally provide such a compact scale, but the theorem is formulated abstractly and applies whenever a suitable compact injective operator  $K$  is available for the law of the source of random noise  $Y_t$ .

## 5.2. Tightness Theorem.

**Definition 5.10.** Given a linear continuous injective operator  $K : H \rightarrow H$  we define

$$\|v\|_K \stackrel{\text{def}}{=} \begin{cases} \|K^{-1}v\|_H & \text{if } v \in K(H) \\ \infty & \text{if } v \notin K(H) \end{cases} \quad . \quad (5.11)$$

Similarly for scalar products, for  $v, w \in K(H)$  we define

$$\langle v, w \rangle_K = \langle K^{-1}v, K^{-1}w \rangle_H \quad . \quad (5.12)$$

**Definition 5.13.** Given Banach spaces  $B_1, B_2$ , we define  $\mathcal{L}(B_1; B_2)$  to be the space of linear continuous operators  $A : B_1 \rightarrow B_2$ . If  $B_1 = B_2$  then we write  $\mathcal{L}(B_1)$

**Theorem 5.14.** Let  $I = [0, T]$ . Suppose that the processes  $\mathfrak{X}^\tau : \Omega \rightarrow C(I; H)$  above defined in Definition 3.27 satisfy the following clauses.

- (1) There is a linear compact operator  $K : H \rightarrow H$  satisfying the requisites in the previous section and such that

$$\mathbb{E}[\|\mathfrak{X}_0\|_K^4] < \infty \quad . \quad (5.15)$$

(2) For all  $x, v \in K(H), t \in I, s \geq 0$

$$D(x, v, t, s) \in K(H) \quad . \quad (5.16)$$

(3) There is a bounded Borel functional  $L = L(x, t)$

$$L : H \times \mathbb{R}^+ \rightarrow \mathcal{L} = \mathcal{L}(H; H) \quad (5.17)$$

such that  $\forall x, v \in K(H)$

$$L(x, t)v \in K(H) \quad ; \quad (5.18)$$

(4) there are constants  $c_3, c > 0$  such that for all  $x, v \in K(H)$

$$\|L(x, t)v\|_K \leq c(\|v\|_K + \|x\|_K\|v\|_H) e^{c_3\|v\|_H} \quad (5.19)$$

(the constant  $c_3$  must be the same as in Hypotheses 3.10).

(5) Moreover, for all  $x, v \in K(H), t \in I, s \in [0, 1]$ ,

$$\|D(x, v, t, s) - \sqrt{s}L(x, t)v\|_K \leq cs \left( \|x\|_K\|v\|_H^2 + \|v\|_K\|v\|_H \right) e^{c_3\sqrt{s}\|v\|_H} \quad . \quad (5.20)$$

(6) There is a constant  $c_d > 1$  such that  $\forall x, v \in H, \forall t \in \mathbb{R}^+, \forall s \in [0, 1]$

$$\|D(x, v, t, s)\|_H \leq c_d\sqrt{s}\|v\|_H \quad , \quad (5.21)$$

$$\sqrt{s}\|v\| \leq 1/c_d \Rightarrow \|D(x, v, t, s) - \sqrt{s}L(x, t)v\|_H \leq c_d s\|v\|_H^2 \quad . \quad (5.22)$$

Then the family  $\mathfrak{X}^\tau$ , for  $\tau \in \mathfrak{T}_T$ , is tight in  $C(I; H)$ .

The assumptions of Theorem 5.14 play two different roles. Item 1 introduces the compact scale  $K$  and controls the initial condition in that scale. Items 2, 3, 4, and 5 ensure that the discrete-time random walk and its first-order approximation are compatible with the  $K$ -structure, so that one can obtain compact-containment estimates at fixed times. Item 6, instead, gives coarser estimates in the ambient Hilbert norm  $H$ ; these are used to control increments and the modulus of continuity, which is the second ingredient in the tightness argument. In this sense, the theorem is an abstract criterion: the first group of assumptions provides compactness, while the last one provides pathwise regularity. To prove this theorem we apply Theorem 4.5 and verify its two hypotheses separately. The proof is in Section 5.4.

*Remark 5.23.* In particular,  $D(x, v, t, s)$  is Frechét differentiable in  $v$  at  $v = 0$ , and the differential is  $\sqrt{s}L(x, t)$ ; and by (5.21) we have

$$\|L(x, t)\|_{\mathcal{L}} \leq c_d \quad , \quad \forall x \in H \quad . \quad (5.24)$$

*Remark 5.25.* The third assumption in Hypotheses 3.10 and the first two hypotheses above imply that

$$\forall t \geq 0 \quad , \quad \mathbb{P}\{\mathfrak{X}_t^\tau \in K(H)\} = 1 \quad . \quad (5.26)$$

### 5.2.1. Corollaries.

**Corollary 5.27.** *Suppose that the hypotheses of Theorem 5.14 hold for any  $T > 0$ ; then the family of processes  $\mathfrak{X}^\tau$ , for  $\tau \in \mathfrak{T}$ , is tight in  $C(\mathbb{R}^+; H)$ .*

*Proof.* We recall this fact. Let  $T > 0$ ; consider the restriction map

$$r_T : C(\mathbb{R}^+; H) \rightarrow C([0, T]; H) \quad (5.28)$$

given by  $r_T f = f|_{[0, T]}$ ; then the topology on  $C(\mathbb{R}^+; H)$  is the initial topology with respect to the maps  $r_n$  and the Banach spaces  $C([0, n]; H)$ , for  $n \in \mathbb{N}$ . (See also Section 5 in [Mennucci] for more details).

Let  $\varepsilon > 0$ , for any  $n \in \mathbb{N}$  by Theorem 5.14 there exists a compact set  $E_n \subseteq C([0, n]; H)$  such that

$$\mathbb{P}\{\mathfrak{X}^\tau \notin r_n^{-1}(E_n)\} \leq \varepsilon 2^{-n} \quad (5.29)$$

let

$$E = \{f \in C(\mathbb{R}^+; H) : \forall n \in \mathbb{N}, r_n f \in E_n\} \quad (5.30)$$

then (by a diagonal argument)  $E$  is precompact in  $C(\mathbb{R}^+; H)$  and

$$\begin{aligned} \mathbb{P}\{\mathfrak{X}^\tau \notin E\} &= \mathbb{P}\{\mathfrak{X}^\tau \in E^c\} = \mathbb{P}\left\{\mathfrak{X}^\tau \in \bigcup_n r_n^{-1}(E_n^c)\right\} \leq \\ &\leq \sum_n \mathbb{P}\{\mathfrak{X}^\tau \in r_n^{-1}(E_n^c)\} = \sum_n \mathbb{P}\{r_n \circ \mathfrak{X}^\tau \notin E_n\} \leq 2\varepsilon \quad \square \end{aligned} \quad (5.31)$$

(More detailed and more general statements can be found in Section 6.3 in [Mennucci].)

Since  $C(\mathbb{R}^+; H)$  is a Fréchet space, by Prokhorov's theorem we obtain this result.

**Corollary 5.32.** *Suppose that the hypotheses of Theorem 5.14 hold for any  $T > 0$ ; the net of processes  $\mathfrak{X}^\tau$ , as r.v. in the Fréchet space  $C(\mathbb{R}^+; H)$ , has narrow limit points.*

**Corollary 5.33.** *By Lemma 5.93 we have*

$$\mathbb{E}[\|\mathfrak{X}_t^\tau\|_K^4] < \infty \quad (5.34)$$

so the process  $\mathfrak{X}_t^\tau$  can be restarted at time  $t$  using  $\mathfrak{X}_t^\tau$  as initial time.

Suppose that the family  $\mathfrak{X}^\tau$  is tight in  $C(I; H)$  (with  $I = [0, T]$  or  $I = [0, \infty)$ ) ; then by Prokhorov's theorem, the set of limit points is not empty; obviously, being  $\mathfrak{X}$  a random variable  $C(I; H)$ , then (almost all) paths are continuous. Something more can be said.

**Corollary 5.35.** *Any limit point  $\mathfrak{X}$  will have a version such that almost all trajectories  $t \mapsto \mathfrak{X}_t$  of  $\mathfrak{X}$  are Hölder continuous functions with an arbitrary exponent smaller than  $1/4$ .*

*Proof.* We use Theorem 6.19 from [Mennucci] with  $p_1 < p_2 = 4$  and use Lemma 5.93 below to state that

$$\lim_\tau \mathbb{E}[\|\mathfrak{X}_t^\tau - \mathfrak{X}_s^\tau\|_H^{p_1}] = \mathbb{E}[\|\mathfrak{X}_t - \mathfrak{X}_s\|_H^{p_1}] \leq c|t - s|^{p_1/2} \quad (5.36)$$

We use the Kolmogorov test<sup>8</sup>: we apply it with  $\delta = p_1, \varepsilon = 1$  and replacing

$$\rho(Z(t), Z(s))^\delta = \|\mathfrak{X}_t - \mathfrak{X}_s\|_H^{p_1} \quad (5.37)$$

so there is a version where paths are Hölder continuous functions with an arbitrary exponent smaller than  $\frac{1}{2} - \frac{1}{p_1}$ .  $\square$

*Remark 5.38.* At this level of generality, we do not expect that there is an unique limit point.

<sup>8</sup>See Theorem 3.3 in [Da Prato and Zabczyk, 2014], or Theorem 6.35 in [Mennucci]

**5.3. A basic example.** We recall this standard result.

**Theorem 5.39** (Donsker's Theorem). *Let  $\xi_1, \xi_2, \xi_3, \dots$  be a sequence of i.i.d. real random variables with mean 0 and variance 1. Let*

$$S_n = \sum_{i=1}^n \xi_i \quad (5.40)$$

and  $S_0 = 0$ . The stochastic process  $S_n$  is known as a random walk.

We rescale and extend the process  $(S_n)_n$  to continuous time  $t \in [0, 1]$ . Define

$$W^N(t) = \frac{S_j}{\sqrt{N}}, \quad t = j/N, \quad j = 0, \dots, N \quad (5.41)$$

and then linearly interpolate

$$W^N(t) = (1-s) \frac{S_j}{\sqrt{N}} + s \frac{S_{j+1}}{\sqrt{N}} = \frac{S_j + s\xi_{j+1}}{\sqrt{N}}, \quad (5.42)$$

for  $j/N \leq t \leq (j+1)/N$  and

$$t = (1-s) \frac{j}{N} + s \frac{j+1}{N} = \frac{j}{N} + s \frac{1}{N} \quad \text{i.e.} \quad s = Nt - j \in [0, 1] \quad ; \quad (5.43)$$

so  $W^N$  is a random variable taking values in  $C([0, 1])$ .

Then, the sequence of random function  $(W^N)_N$  converges narrowly to a random function  $W$  on  $C([0, 1])$ , as  $N \rightarrow \infty$ ; this  $W$  is the standard Wiener Process.<sup>9</sup>

Theorem 9.1 in [Billingsley, 2013] uses the above as a method to define Wiener Process; by Kolmogorov's theorem,  $W$  has a version where almost all paths are continuous. Other sources call the above result *Donsker's Theorem*.

The random walk  $(S_n)_n$  can be recast into a continuous time process in different ways.

- We may define

$$W^N(t) = \frac{S_{\lfloor Nt \rfloor}}{\sqrt{N}}, \quad t \in [0, 1] \quad (5.44)$$

and consider  $W^N$  as random variables taking values in the Skorokhod space  $\mathbb{D}[0, 1]$ .

- We may define

$$W^N(t) = \frac{S_j + \sqrt{s}\xi_{j+1}}{\sqrt{N}} \quad (5.45)$$

for  $t, s$  defined as in (5.43).

With those (and other) interpolations, the thesis of Theorem 5.39 holds as well.

Note that the interpolation (5.45) has a benefit: if the variables  $\xi_j \sim N(0, 1)$  then  $W^N(t) \sim N(0, t)$ .

*Remark 5.46.* The above construction of  $W^N$  in Theorem 5.39, when using the interpolation method (5.45) is a special case of the random walk  $\mathfrak{X}_t^{\tau^N}$  where  $\tau^N = \{t_j = j/N : j = 0, \dots, N\}$ ,  $\mathfrak{X}_0 = 0$ ,  $H = \mathbb{R}$  and  $D(x, v, t, s) = \sqrt{s}v$ . In this case we may choose  $L$  to be the identity:  $L(x, t)v = v$ .

<sup>9</sup>A possible proof may be found in Theorem 9.1 in [Billingsley, 2013] (this uses the linear approximations (5.42)). Note that *Wiener Process* is also known as *Brownian Motion* in some texts, as [Hsu, 2002] or Chapter 12 in [Breiman, 1968].

Suppose that the r.v.  $Y_t$  and  $\xi_n$  all have the same law. Indeed, in equation (1.3) we have

$$\begin{aligned} X_{j+1}^{\tau^N} &= X_j^{\tau^N} + D\left(X_j^{\tau^N}, Y_{t_j}, t_j, (t_{j+1} - t_j)\right) = \\ &= X_j^{\tau^N} + \sqrt{(t_{j+1} - t_j)}Y_{t_j} = X_j^{\tau^N} + \frac{1}{\sqrt{N}}Y_{t_j} \quad . \end{aligned} \quad (5.47)$$

Then we interpolate using

$$\begin{aligned} \mathfrak{X}_t^{\tau^N} &= X_j^{\tau^N} + D\left(X_j^{\tau^N}, Y_{t_j}, t_j, (t - t_j)\right) \\ &= X_j^{\tau^N} + \sqrt{(t - t_j)}Y_{t_j} = X_j^{\tau^N} + \sqrt{s/N}Y_{t_j} \end{aligned} \quad (5.48)$$

for  $j/N \leq t \leq (j+1)/N$ ; in the last step we used (5.43). Hence the process  $(\mathfrak{X}_t^{\tau^N})_t$  and  $(W^N)$  are identically distributed.

So we can derive a corollary of Theorem 5.14 as follows.

**Corollary 5.49.** *Let  $H = \mathbb{R}^d$ , let  $I = [0, T]$ , and let  $(Y_t)_{t \in \mathbb{R}^+}$  be i.i.d.  $H$ -valued random variables. We assume that they are centered and that, for the constants  $c_t, c_3 > 0$  fixed in Hypotheses 3.10,*

$$\mathbb{E}\left[\|Y_t\|_H^4 e^{4c_3 c_t \|Y_t\|_H}\right] < \infty \quad . \quad (5.50)$$

*Let  $\mathfrak{X}_0$  be an  $H$ -valued random variable, independent of all  $Y_t$ , and consider the processes  $\mathfrak{X}^\tau$  defined as in Definition 3.27. Assume that the following clauses hold.*

(1)

$$\mathbb{E}[\|\mathfrak{X}_0\|_H^4] < \infty \quad . \quad (5.51)$$

(3) *There is a constant  $c > 0$  such that for all  $x, v \in H$ ,  $t \in I$ ,  $s \in [0, 1]$ ,*

$$\|D(x, v, t, s) - \sqrt{s}v\|_H \leq cs(\|x\|_H + 1)\|v\|_H^2 \quad . \quad (5.52)$$

(4) *There is a constant  $c_d > 1$  such that for all  $x, v \in H$ ,  $t \in \mathbb{R}^+$ ,  $s \in [0, 1]$ ,*

$$\begin{aligned} \|D(x, v, t, s)\|_H &\leq c_d \sqrt{s} \|v\|_H \quad , \\ \sqrt{s} \|v\|_H \leq 1/c_d &\Rightarrow \|D(x, v, t, s) - \sqrt{s}v\|_H \leq c_d s \|v\|_H^2 \quad . \end{aligned} \quad (5.53)$$

*Then the family  $\mathfrak{X}^\tau$ , for  $\tau \in \mathfrak{T}_T$ , is tight in  $C(I; H)$ .*

*Proof.* Since  $H$  is finite-dimensional, the identity  $K = \text{Id}_H$  is a compact operator and  $K(H) = H$ . We choose  $L(x, t) = \text{Id}_H$ . Then conditions (2), (2L), and (3L) in Theorem 5.14 are automatic; the remaining assumptions are exactly those of Theorem 5.14. Hence Theorem 5.14 applies and yields the conclusion.  $\square$

In the special case  $D(x, v, t, s) = \sqrt{s}v$ , we recover the tightness part of Donsker's theorem. The corollary therefore extends that tightness result to a rescaled nonlinear random walk. All the corollaries stated in Subsection 5.2.1 then apply.

We add an important remark.

**Proposition 5.54.** *There is no choice of common probability space where to define  $Y_t$  and  $W_t$  and such that the approximating processes  $W^N$  defined above would converge to  $W$  in probability.*

**5.4. Proof of Theorem 5.14.** The proof is organized as follows. The first step establishes the compactness requirement (first hypothesis in Theorem 4.5) at fixed times, using the stronger  $K(H)$ -topology: Lemma 5.55 gives recursive  $K$ -moment bounds for the discrete variables  $X_n^\tau$ , and Corollary 5.80 transfers these estimates to the interpolated process  $\mathfrak{X}^\tau$ , yielding the compact sets required in the first clause of Theorem 4.5. The second step controls the modulus of continuity in the ambient Hilbert norm. We first prove second- and fourth-moment bounds for increments (Lemmas 5.89 and 5.93), then combine them with an Etemadi-type maximal estimate adapted to the random walk and to its interpolation (Lemma 5.109 and Corollary 5.120) to eventually obtain the probability bound in (4.7). The following three subsections are organized according to this scheme.

**5.4.1. Proof of Theorem 5.14, step 1.** In this section we prove that, under the hypotheses of Theorem 5.14, the first hypothesis in Theorem 4.5 is satisfied. We will use this Lemma in two ways, with  $K$  being the compact operator defined above in the hypotheses of Theorem 5.14, but also with  $K$  being the identity.

**Lemma 5.55.** *Let  $K : H \rightarrow H$  a linear injective operator (not necessarily compact). Let  $\|v\|_K$  be defined in eqn. (5.11). We assume that for all  $x, v \in K(H)$ ,  $t, s > 0$*

$$D(x, v, t, s) \in K(H) \text{ , } L(x, t)v \in K(H) \quad (5.56)$$

(these are items 2 and 3 of Theorem 5.14), while we rewrite item 5 in this form: there are constants  $c_{1D}, c_{2D} \geq 0$  such that for all  $x, v \in K(H)$ ,  $s \in [0, 1]$

$$\|D(x, v, t, s) - sL(x, t)v\|_K \leq s \left( c_{1D} \|x\|_K \|v\|_H^2 + c_{2D} \|v\|_K \|v\|_H \right) e^{c_3 \sqrt{s} \|v\|_H} \quad (5.57)$$

and we rewrite item 4: there are constants  $c_{1L}, c_{2L} \geq 0$  such that for all  $x, v \in K(H)$ ,

$$\|L(x, t)v\|_K \leq (c_{1L} \|x\|_K \|v\|_H + c_{2L} \|v\|_K) e^{c_3 \|v\|_H} \quad (5.58)$$

Define the following objects: let  $\tau \in \mathfrak{T}$ ; fix  $m \geq 0$  and <sup>10</sup>  $F \in \mathcal{F}_{t_m}$  with  $\mathbb{P}(F) > 0$ ; we will write  $\mathbb{E}_F$  for the expectation computed using the conditional probability  $\mathbb{P}(\cdot|F)$ ; consider  $n \geq m$ ; let

$$e_m = \mathbb{E}_F[\|X_m^\tau\|_K^2] \quad , \quad b_n \stackrel{\text{def}}{=} \mathbb{E}_F[\|X_n^\tau - X_m^\tau\|_K^2] \quad (5.59)$$

Then we have two theses.

- If  $c_{1D} = c_{1L} = 0$  then

$$b_n \leq \left( e^{c_5(t_n - t_m)} - 1 \right) \quad (5.60)$$

- Instead if  $(c_{1L} + c_{1D}) > 0$  then

$$b_n \leq (e_m + 1) \left( e^{c_5(t_n - t_m)} - 1 \right) \quad (5.61)$$

where  $c_5 > 0$  depends only on  $c_{1L}, c_{2L}, c_{1D}, c_{2D}$ , on  $\tilde{c}(4, 4c_3)$  from Prop. 3.15, on  $K$  and the law  $\gamma$  of  $Y_t$ ; but  $c_5$  does not depend on  $e_m$ , on  $F$ , and on  $\tau$ .

<sup>10</sup>Recall from Proposition 3.31 that  $\mathcal{F}_t$  is the  $\sigma$ -algebra generated by  $\mathfrak{X}_0$  and by  $Y_s$  for  $s < t$ .

*Remark 5.62.* Recall that

$$\sqrt{\mathbb{E}_F[\|X_n^\tau\|_K^2]} \leq \sqrt{\mathbb{E}_F[\|X_n^\tau - X_m^\tau\|_K^2]} + \sqrt{\mathbb{E}_F[\|X_m^\tau\|_K^2]} \quad (5.63)$$

(or otherwise using Lemma A.1 in Appendix A) we get

$$\mathbb{E}_F[\|X_n^\tau\|_K^2] \leq (\sqrt{e_m} + \sqrt{b_n})^2 \leq 2(e_m + b_n) \quad (5.64)$$

*Proof of Lemma 5.55.* For  $t \geq t_m$  we define

$$a_{K,\alpha} = \mathbb{E}_F[\|Y_t\|_K^\alpha] = \mathbb{E}[\|Y_t\|_K^\alpha], \quad a_\alpha = \mathbb{E}_F[\|Y_t\|^\alpha] = \mathbb{E}[\|Y_t\|^\alpha] \quad (5.65)$$

where the equality derives by independence; by Hypotheses 3.10 these are finite for  $\alpha \leq 4$ . For readability, we write  $X_n$  instead of  $X_n^\tau$ , we write  $\tilde{X}_n$  instead of  $X_n^\tau - X_0^\tau$  and  $\delta_n = t_{n+1} - t_n$ ; we abbreviate

$$D_n = D(X_n, Y_{t_n}, t_n, \sqrt{\delta_n}) \quad (5.66)$$

$$A_n = D_n - \sqrt{\delta_n} L(t_n, X_n) Y_{t_n} \quad (5.67)$$

By (5.64) and (5.57) using Lemma A.1 and Proposition 3.15, when  $c_3 > 0$

$$\begin{aligned} \mathbb{E}_F[\|A_n\|_K^2] &\leq 2c_{1D}^2 \delta_n \mathbb{E}_F \left[ \|X_n\|_K^2 \|Y_{t_n}\|_H^4 e^{2c_3 \sqrt{\delta_n} \|Y_{t_n}\|_H} \right] + \\ &\quad 2c_{2D}^2 \delta_n \mathbb{E}_F \left[ \|Y_{t_n}\|_K^2 \|Y_{t_n}\|_H^2 e^{2c_3 \sqrt{\delta_n} \|Y_{t_n}\|_H} \right] \leq \\ &\leq 2c_{1D}^2 \mathbb{E}_F [\|X_n\|_K^2] \mathbb{E} \left[ \|\sqrt{\delta_n} Y_{t_n}\|_H^4 e^{2c_3 \|\sqrt{\delta_n} Y_{t_n}\|_H} \right] + \\ &\quad 2c_{2D}^2 \delta_n \sqrt{\mathbb{E}[\|Y_{t_n}\|_K^4]} \sqrt{\mathbb{E}[\|\sqrt{\delta_n} Y_{t_n}\|_H^4 e^{4c_3 \|\sqrt{\delta_n} Y_{t_n}\|_H}]} \leq \\ &\leq \delta_n^2 \left( 4c_{1D}^2 (b_n + e_m) \tilde{c}(4, 2c_3) + 2c_{2D}^2 \sqrt{\tilde{c}(4, 4c_3) a_{4,K}} \right) \end{aligned} \quad (5.68)$$

Summarizing we have

$$\mathbb{E}_F[\|A_n\|_K^2] \leq \delta_n^2 c_4^2 (c_{1D}^2 (b_n + e_m) + 1) \quad (5.69)$$

where  $c_4$  depends only on  $c_{2D}, c_3$ , on  $\tilde{c}$  from Corollary 3.15, on  $c_t > 0$  from Hypotheses 3.10 and Definition 3.23; but  $c_4$  does not depend on  $F$ , on  $c_{1D}$  and  $\tau$ .

Similarly using (5.58)

$$\begin{aligned} \delta_n \mathbb{E}_F[\|L(X_n, t) Y_{t_n}\|_K^2] &\leq 2c_{1L}^2 \delta_n \mathbb{E}_F \left[ \|X_n\|_K^2 \|Y_{t_n}\|_H^2 e^{2c_3 \sqrt{\delta_n} \|Y_{t_n}\|_H} \right] + \\ &\quad 2c_{2L}^2 \delta_n \mathbb{E} \left[ \|Y_{t_n}\|_K^2 e^{2c_3 \sqrt{\delta_n} \|Y_{t_n}\|_H} \right] \leq \\ &\leq 2c_{1L}^2 \mathbb{E}_F [\|X_n\|_K^2] \mathbb{E} \left[ \|\sqrt{\delta_n} Y_{t_n}\|_H^2 e^{2c_3 \|\sqrt{\delta_n} Y_{t_n}\|_H} \right] + \\ &\quad 2c_{2L}^2 \delta_n \sqrt{\mathbb{E}[\|Y_{t_n}\|_K^4]} \sqrt{\mathbb{E}[e^{4c_3 \|\sqrt{\delta_n} Y_{t_n}\|_H}]} \leq \\ &\leq \delta_n \left( 4c_{1L}^2 (b_n + e_m) \tilde{c}(2, 2c_3) + 2c_{2L}^2 \sqrt{\tilde{c}(0, 4c_3) a_{4,K}} \right) \end{aligned} \quad (5.70)$$

summarized to

$$\delta_n \mathbb{E}_F[\|L(X_n, t) Y_{t_n}\|_K^2] \leq \delta_n c_4^2 (c_{1L}^2 (b_n + e_m) + 1) \quad (5.71)$$

possibly enlarging  $c_4$ , that now depends also on  $c_{2L}$ .

We estimate iteratively. We begin by expressing

$$\begin{aligned}\|\tilde{X}_{n+1}\|_K^2 &= \|D_n + \tilde{X}_n\|_K^2 = \|\tilde{X}_n + \sqrt{\delta_n}L(X_n, t)Y_{t_n} + A_n\|_K^2 = \\ &= \|\tilde{X}_n\|_K^2 + \delta_n\|L(X_n, t)Y_{t_n}\|_K^2 + \|A_n\|_K^2 + \\ &+ 2\sqrt{\delta_n}\langle \tilde{X}_n, L(X_n, t)Y_{t_n} \rangle_K + 2\langle \tilde{X}_n, A_n \rangle_K + \\ &+ 2\sqrt{\delta_n}\langle A_n, L(X_n, t)Y_{t_n} \rangle_K\end{aligned}\quad (5.72)$$

we then compute the expectation; we note that

$$\mathbb{E}_F[\langle \tilde{X}_n, L(X_n, t)Y_{t_n} \rangle_K] = 0 \quad (5.73)$$

because  $Y_{t_n}$  has zero average and is independent of  $F$ , of  $X_n$  and  $X_m$ ; whereas

$$\begin{aligned}\mathbb{E}_F[\|\tilde{X}_n\|_K^2] &= b_n \\ \delta_n \mathbb{E}_F[\|L(X_n, t)Y_{t_n}\|_K^2] &\leq \delta_n c_4^2 (c_{1L}^2 (b_n + e_m) + 1) \\ \mathbb{E}_F[\|A_n\|_K^2] &\leq \delta_n^2 c_4^2 (c_{1D}^2 (b_n + e_m) + 1) \\ \mathbb{E}_F[\langle A_n, \sqrt{\delta_n}L(X_n, t)Y_{t_n} \rangle_K] &\leq \sqrt{\mathbb{E}_F[\|A_n\|_K^2]} \sqrt{\mathbb{E}_F[\delta_n\|L(X_n, t)Y_{t_n}\|_K^2]} \\ &\leq \delta_n^{3/2} c_4^2 (c_1^2 (b_n + e_m) + 1) \\ \mathbb{E}_F[\langle \tilde{X}_n, A_n \rangle_K] &\leq \sqrt{b_n} \sqrt{\mathbb{E}_F[\|A_n\|_K^2]}\end{aligned}$$

where  $c_1 = \max\{c_{1L}, c_{1D}\}$ .

In this last line, if  $c_{1D} = c_{1L} = 0$  then again we use  $\sqrt{s} \leq s + 1$  and equation (5.69) so

$$\mathbb{E}_F[\langle \tilde{X}_n, A_n \rangle_K] \leq \sqrt{b_n} \sqrt{\mathbb{E}_F[\|A_n\|_K^2]} \leq \delta_n c_4 \sqrt{b_n} \leq \delta_n c_4 (b_n + 1) \quad (5.75)$$

so (recalling that  $\delta_n \leq c_t$ , the constant from Hypotheses 3.10) we estimate as follows

$$b_{n+1} \leq b_n + c_5 \delta_n (1 + b_n) = b_n (1 + c_5 \delta_n) + c_5 \delta_n \quad (5.76)$$

which, by the Lemma A.29 in Appendix A (shifting the sequence), implies equation (5.60).

Instead if  $c_1 > 0$  we note that

$$s(c_1^2 s + 2a) \leq c_1^2 s^2 + 2as + a^2/c_1^2 = (c_1 s + a/c_1)^2 \quad (5.77)$$

hence using equation (5.69) and setting  $s = b_n, a = (c_1^2 e_m + 1)/2$

$$\mathbb{E}_F[\langle \tilde{X}_n, A_n \rangle_K] \leq \delta_n c_4 \sqrt{b_n} \sqrt{(c_1^2 (b_n + e_m) + 1)} \leq \delta_n c_4 \left( c_1 b_n + c_1 \frac{e_m}{2} + \frac{1}{2c_1} \right) \quad (5.78)$$

Eventually we estimate as follows

$$b_{n+1} \leq b_n (1 + c_5 \delta_n) + c_5 \delta_n (e_m + 1) \quad (5.79)$$

which, by the Lemma A.29 in Appendix A (shifting the sequence), implies equation (5.61).  $\square$

**Corollary 5.80.** *Let  $m = 0, F = \Omega$ , then by equation (5.64) and equation (5.61) we obtain that*

$$\mathbb{E}[\|X_n^\tau\|_K^2] \leq (e_0 + 1)e^{c_5 t_n} \quad (5.81)$$

with  $e_0 = \mathbb{E}[\|\mathfrak{X}_0\|_K^2] < \infty$ , under assumption (5.15); moreover as explained in Remark 3.32 we have

$$\mathbb{E}[\|\mathfrak{X}_t^\tau\|_K^2] \leq (e_0 + 1)e^{c_5 t} \quad (5.82)$$

for all  $t \geq 0$ .

*Conclusion of step 1.* So to conclude the first step, we consider a process  $\mathfrak{X}^\tau$  and a time  $T > 0$ ; let  $\varepsilon > 0$ , for  $0 \leq t \leq T, r > 0$  we have then by Markov inequality

$$\mathbb{P}\{\|\mathfrak{X}_t^\tau\|_K \geq r\} \leq \frac{\mathbb{E}[\|\mathfrak{X}_t^\tau\|_K^2]}{r^2} \leq \frac{1}{r^2} c_K \quad (5.83)$$

with

$$c_K = (e_0 + 1)e^{c_5 T} \quad (5.84)$$

so setting  $r_j = \sqrt{(c_K 2^j)/\varepsilon}$

$$\mathbb{P}\{\mathfrak{X}_{a_j}^\tau \notin D_K(0, r_j)\} < \varepsilon 2^{-j} \quad (5.85)$$

and this satisfies the first hypothesis in Theorem 4.5.  $\square$

**5.4.2. Proof: Lemmas for step 2.** In this section we prove some powerful Lemmas that then will be used to prove that the second hypothesis in Theorem 4.5 is satisfied.

*Remark 5.86.* Consider item 6 of Theorem 5.14; note that, for  $s \in [0, 1]$ , by equations (5.21) and (5.24),

$$\begin{aligned} \|D(x, v, t, s) - \sqrt{s}L(x, t)v\|_H &\leq \|D(x, v, t, s)\|_H + \|\sqrt{s}L(x, t)v\|_H \\ &\leq 2c_d\sqrt{s}\|v\|_H \leq 2c_d^2 s\|v\|_H^2 \end{aligned} \quad (5.87)$$

for  $\sqrt{s}\|v\| \geq 1/c_d$  so adding equation (5.22) we obtain

$$\forall x, v \in H, \forall s \in [0, 1], t \geq 0, \|D(x, v, t, s) - \sqrt{s}L(x, t)v\|_H \leq 2c_d^2 s\|v\|_H^2 \quad (5.88)$$

**Lemma 5.89.** Assume item 6 of Theorem 5.14; define the objects as in Lemma 5.55, with  $K$  being the identity, recall that in this case

$$b_n \stackrel{\text{def}}{=} \mathbb{E}_F[\|X_n^\tau - X_m^\tau\|_H^2] \quad ; \quad (5.90)$$

then for  $n \geq m$

$$b_n \leq \left(e^{c_5(t_n - t_m)} - 1\right) \quad (5.91)$$

In particular for  $0 \leq t_m \leq t_n \leq T$  we have

$$b_n \leq c_6(t_n - t_m) \quad (5.92)$$

*Proof.* Use Remark 5.86 and Remark 5.23; apply Lemma 5.55 with  $K$  being the identity,  $c_{1L} = c_{1D} = c_3 = 0$ ,  $c_{2L} = c_{2D} = 2c_d^2$ ; we obtain the constant  $c_5 > 0$  and hence we set  $c_6 = c_5 e^{c_5 T}$ .  $\square$

**Lemma 5.93.** Assume item 6 of Theorem 5.14; We fix  $\tau \in \mathfrak{T}$ ; we fix  $m \geq 0$  and  $F \in \mathcal{F}_{t_m}$ ; we will write  $\mathbb{E}_F$  for the expectation computed using the conditional probability  $\mathbb{P}(\cdot|F)$ ; consider  $n \geq m$ ; letting

$$b_n \stackrel{\text{def}}{=} \mathbb{E}_F[\|X_n^\tau - X_m^\tau\|_H^2] \quad , \quad (5.94)$$

suppose that there is a constant  $c_6$  such that

$$b_n \leq c_6(t_n - t_m) \quad (5.95)$$

for  $0 \leq t_m \leq t_n \leq T$  (as in equation (5.92)) and eventually let

$$q_n \stackrel{\text{def}}{=} \mathbb{E}_F[\|X_n^\tau - X_m^\tau\|_H^4] \quad . \quad (5.96)$$

We prove that, for  $0 \leq t_n \leq t_m \leq T$ ,

$$q_n \leq (c_7 + 2c_8)g(t_n - t_m) \quad (5.97)$$

where

$$g(t) = \frac{e^{c_7 t} - 1 - c_7 t}{c_7^2} \quad . \quad (5.98)$$

and where  $c_8, c_7$  depend only on  $c_6, c_d$  and the fourth moment of  $Y_t$ .

*Proof of Lemma.* For  $t \geq t_m$  we define

$$a_\alpha = \mathbb{E}_F[\|Y_t\|^\alpha] = \mathbb{E}[\|Y_t\|^\alpha] \quad (5.99)$$

where the equality derives by independence.

Again, for readability, we write  $X_n$  instead of  $X_n^\tau$ , and  $\tilde{X}_n$  instead of  $X_n^\tau - X_m^\tau$ ,  $\delta_n = t_{n+1} - t_n$  and

$$D_n = D(X_n, Y_{t_n}, t_n, \sqrt{\delta_n}) \quad (5.100)$$

and  $\|x\| = \|x\|_H$ . We compute

$$\begin{aligned} \|\tilde{X}_{n+1}\|^4 &= \|\tilde{X}_n + D_n\|^4 = (\|\tilde{X}_n\|^2 + 2\langle \tilde{X}_n, D_n \rangle + \|D_n\|^2)^2 = \\ &= \|\tilde{X}_n\|^4 + 4\langle \tilde{X}_n, D_n \rangle^2 + \|D_n\|^4 + \\ &4\|\tilde{X}_n\|^2 \langle \tilde{X}_n, D_n \rangle + 4\langle \tilde{X}_n, D_n \rangle \|D_n\|^2 + 2\|\tilde{X}_n\|^2 \|D_n\|^2 \end{aligned}$$

then we compute integrals; for the fourth term, since

$$\mathbb{E}_F[\|\tilde{X}_n\|^2 \langle \tilde{X}_n, L(X_n, t_n)Y_{t_n} \rangle] = 0 \quad (5.102)$$

by independence, then

$$\mathbb{E}_F[\|\tilde{X}_n\|^2 \langle \tilde{X}_n, D_n \rangle] = \mathbb{E}_F[\|\tilde{X}_n\|^2 \langle \tilde{X}_n, D_n - \sqrt{\delta_n}L(X_n, t_n)Y_{t_n} \rangle] \quad (5.103)$$

so by equation (5.88)

$$\begin{aligned} |\mathbb{E}_F[\|\tilde{X}_n\|^2 \langle \tilde{X}_n, D_n \rangle]| &\leq \mathbb{E}_F[\|\tilde{X}_n\|^3 \|D_n - \sqrt{\delta_n}L(X_n, t_n)Y_{t_n}\|] \leq \\ &\leq 2c_d^2 \delta_n \mathbb{E}_F[\|\tilde{X}_n\|^3 \|Y_{t_n}\|^2] = \\ &= 2c_d^2 \delta_n \mathbb{E}_F[\|\tilde{X}_n\|^3] \mathbb{E}[\|Y_{t_n}\|^2] \leq \\ &\leq 2c_d^2 \delta_n a_2 \sqrt{\mathbb{E}_F[\|\tilde{X}_n\|^2] \mathbb{E}_F[\|\tilde{X}_n\|^4]} \leq \\ &\leq 2c_d^2 \delta_n a_2 \sqrt{q_n} \sqrt{b_n} \end{aligned}$$

(again by using independence in the third step). For the other terms, using equation (5.21),

$$\begin{aligned} \mathbb{E}_F[\langle \tilde{X}_n, D_n \rangle^2] &\leq \mathbb{E}_F[\|\tilde{X}_n\|^2 \|D_n\|^2] \leq \\ &\leq c_d^2 \mathbb{E}_F[\|\tilde{X}_n\|^2 \|\sqrt{\delta_n}Y_{t_n}\|^2] \leq c_d^2 a_2 b_n \delta_n \quad , \\ \mathbb{E}_F[\|D_n\|^4] &\leq c_d^4 a_4 \delta_n^2 \quad , \\ \mathbb{E}_F[\langle \tilde{X}_n, D_n \rangle \|D_n\|^2] &\leq \mathbb{E}_F[\|\tilde{X}_n\| \|D_n\|^3] \leq \\ &\leq c_d^3 \delta_n^{3/2} \mathbb{E}_F[\|\tilde{X}_n\| \|Y_n\|^3] \leq c_d^3 a_3 \sqrt{b_n} \delta_n^{3/2} \quad , \end{aligned}$$

Eventually we use  $b_n \leq c_6 t_n$  and note that  $t_n \geq \delta_n$  then  $t_n \delta_n \geq \sqrt{t_n} \delta_n^{3/2}$  and  $t_n \delta_n \geq \delta_n^2$ ; hence (defining  $c_7, c_8 > 0$  appropriately), summarizing

$$q_{n+1} \leq q_n + (c_7 \sqrt{q_n t_n} + c_8 t_n) \delta_n \quad (5.106)$$

using Lemma A.12 in Appendix A (shifting the sequence) we obtain equation (5.97).  $\square$

We recall Etemadi's inequality [Etemadi, 1985] in the version of Theorem 22.5 in [Billingsley, 1995].

**Lemma 5.107** (Etemadi's inequality). *Suppose that  $S_n$  is a process taking value in normed space, and it is the sum  $S_n = Y_1 + \dots + Y_n$  of i.i.d. r.v.  $(Y_n)_n$ ; then for  $\varepsilon > 0$  we have*

$$\mathbb{P}\left(\max_{1 \leq k \leq l} |S_k| \geq 3\varepsilon\right) \leq 3 \max_{1 \leq k \leq l} \mathbb{P}(|S_k| \geq \varepsilon) \quad (5.108)$$

This is a keys step in the proof of Donsker theorem, but we cannot use it in this form. To conclude the proof of Theorem 5.14 we need to prove a similar result, adapted to our process and hypotheses.

**Lemma 5.109.** *In the hypotheses of Theorem 5.14, with  $\tau \in \mathfrak{T}$  (as in previous Lemmas), we fix  $T, \varepsilon > 0$ , we fix  $l \geq m > 0$  integers such that  $t_l \leq T$ , then*

$$\mathbb{P}\left(\max_{m \leq k \leq l} \|X_k^\tau - X_{m-1}^\tau\| > 3\varepsilon\right) \leq \frac{c_{10}}{\varepsilon^4} g(t_l - t_{m-1}) \quad (5.110)$$

where again  $g$  was defined in equation (5.98); and  $c_{10}$  depends only on the constants in previous Lemmas.

*Proof.* Let  $X = X^\tau$  for simplicity, and

$$\tilde{X}_k = X_k - X_{m-1} \quad , \quad (5.111)$$

note that

$$\tilde{X}_n - \tilde{X}_j = X_n - X_j \quad . \quad (5.112)$$

Let

$$A_m = \{\|\tilde{X}_m\| > 3\varepsilon\} \quad (5.113)$$

and for  $j = m+1, \dots, l$  let

$$A_j = \left\{ \max_{m \leq i \leq j-1} \|\tilde{X}_i\| \leq 3\varepsilon \wedge \|\tilde{X}_j\| > 3\varepsilon \right\} \quad (5.114)$$

so

$$\bigcup_{j=m}^l A_j = \left\{ \max_{m \leq k \leq l} \|\tilde{X}_k\| > 3\varepsilon \right\} \quad (5.115)$$

then, further disintegrating,

$$\begin{aligned} \mathbb{P}\left(\max_{m \leq k \leq l} \|\tilde{X}_k\| > 3\varepsilon\right) &\leq \mathbb{P}(\|\tilde{X}_l\| \geq \varepsilon) + \sum_{j=m}^l \mathbb{P}(A_j \cap \{\|\tilde{X}_l\| < \varepsilon\}) \leq \\ &\leq \mathbb{P}(\|\tilde{X}_l\| \geq \varepsilon) + \sum_{j=m}^l \mathbb{P}(A_j \cap \{\|X_l - X_j\| > 2\varepsilon\}) = \\ &= \mathbb{P}(\|\tilde{X}_l\| \geq \varepsilon) + \sum_{j=1}^l \mathbb{P}(A_j) \mathbb{P}(\{\|X_l - X_j\| > 2\varepsilon\} \mid A_j) \end{aligned}$$

by Markov

$$\mathbb{P}(\{\|X_l - X_j\| > 2\varepsilon\} \mid A_j) \leq \frac{1}{2^4 \varepsilon^4} \mathbb{E}[\|X_l - X_j\|^4 \mid A_j] \quad . \quad (5.117)$$

We use Lemma 5.89 with  $K$  the identity and  $F = A_j$ ; note that indeed  $A_j \in \mathcal{F}_{t_j}$ ; having set  $T > 0$  we obtain equation (5.91) that is equation (5.95). So equation (5.95) is satisfied and we can apply Lemma 5.93 to obtain the equation (5.97) in the thesis in Lemma 5.93, that we rewrite as

$$\mathbb{E}[\|X_n - X_j\|^4 \mid A_j] \leq (c_7 + 2c_8)g(t_n - t_j) \quad . \quad (5.118)$$

Plugging it all in

$$\begin{aligned} & \sum_{j=m}^l \mathbb{P}(A_j) \mathbb{P}(\{\|X_l - X_j\| > 2\varepsilon\} \mid A_j) \leq \\ & \frac{1}{2^4 \varepsilon^4} (c_7 + 2c_8)g(t_l - t_{m-1}) \sum_{j=m}^l \mathbb{P}(A_j) \quad . \end{aligned} \quad (5.119)$$

Similarly we deal with the first term  $\mathbb{P}(\|\tilde{X}_l\| \geq \varepsilon)$ . □

We then prove the same result for the process  $\mathfrak{X}^\tau$ .

**Corollary 5.120.** *In the hypotheses of the previous Lemma, fix  $\varepsilon > 0$ , then for  $t_m \in \tau$  and  $t_m \leq s \leq T$*

$$\mathbb{P}\left(\sup_{t_m < t \leq s} \|\mathfrak{X}_t^\tau - \mathfrak{X}_{t_m}^\tau\| > 3\varepsilon\right) \leq \frac{c_{10}}{\varepsilon^4} g(s - t_m) \quad (5.121)$$

*Proof.* Fix  $\tau \in \mathfrak{T}_T$  and  $t_m \in \tau$ . For  $t_m \leq s \leq T$  let

$$A_s^\tau = A_s \stackrel{\text{def}}{=} \left\{ \sup_{t_m \leq t \leq s} \|\mathfrak{X}_t^\tau - \mathfrak{X}_{t_m}^\tau\| > 3\varepsilon \right\} \quad (5.122)$$

then

$$A_s = \left\{ \sup_{t_m \leq t \leq s, t \in \mathbb{Q}} \|\mathfrak{X}_t^\tau - \mathfrak{X}_{t_m}^\tau\| > 3\varepsilon \right\} \quad (5.123)$$

since trajectories are continuous. Then for  $s_1 < s_2$  we have  $A_{s_1} \subseteq A_{s_2}$  and moreover

$$\bigcup_{s_1 < s_2} A_{s_1} = A_{s_2} \quad (5.124)$$

again using the fact that trajectories are continuous; hence we obtain left-continuity

$$\sup_{s_1 < s_2} \mathbb{P}(A_{s_1}) = \lim_{s_1 \rightarrow s_2^-} \mathbb{P}(A_{s_1}) = \mathbb{P}(A_{s_2}) \quad . \quad (5.125)$$

As noted in Remark 3.32 if  $\hat{t} > 0$  (and not necessarily  $\hat{t} \in \mathbb{Q}$ ), if we add  $\hat{t}$  to  $\tau$  and obtain  $\hat{\tau} = \tau \cup \{\hat{t}\}$  then

$$\mathfrak{X}_t^{\hat{\tau}} = \mathfrak{X}_t^\tau \quad \forall t \leq \hat{t} \quad , \quad (5.126)$$

so

$$A_t^{\hat{\tau}} = A_t^\tau \quad \forall t \leq \hat{t} \quad , \quad (5.127)$$

but then we can apply the previous Lemma and the above left-continuity to say that

$$\mathbb{P}(A_t^{\hat{\tau}}) = \mathbb{P}(A_t^\tau) \leq \frac{c_{10}}{\varepsilon^4} g(t - t_m) \quad . \quad (5.128)$$

□

We recall this other fundamental Lemma (that is key to Theorem 8.3 in [Billingsley, 2013]).

**Lemma 5.129.** *Suppose  $E$  is a normed vector space,  $I = [a, b]$ ; let  $\eta, \varepsilon, v > 0$  with  $v \in \mathbb{N}$ ; suppose  $\mu$  is a probability measure on the space  $C = C(I; E)$ , let  $a = s_0 < s_1 < \dots < s_v = b \in I$  with*

$$(s_{i+1} - s_i) \geq \eta \quad \text{for } i = 2, \dots, v-2 \quad (5.130)$$

then

$$\mu\{x \in C : \omega(x, \eta) \geq 3\varepsilon\} \leq \sum_{i=0}^{v-1} \mu\left\{x \in C : \sup_{s_i \leq s < s_{i+1}} \|x(s) - x(s_i)\|_E \geq \varepsilon\right\} \quad (5.131)$$

(For the proof, see the Corollary after Theorem 8.3 in [Billingsley, 2013]). Note that the inequality (5.130) need not hold for  $i = 1, i = v-1$ .

5.4.3. *Proof of Theorem 5.14, step 2.* Now that we have proved the powerful Lemmas, we prove the second hypothesis in Theorem 4.5, that is eqn. (4.7); to this end, we fix  $\varepsilon_0 > 0, \varepsilon_1 > 0$ ; there is an  $\eta > 0$  with  $\eta \in \mathbb{Q}, \eta < c_t, \eta < T/2$  such that

$$9^4 [T/\eta] c_{10} \frac{g(\eta)}{\varepsilon_0^4} < \varepsilon_1 \quad (5.132)$$

where  $g$  was defined in eqn. (5.98) in Lemma 5.93; eqn. (4.7) will be satisfied with  $A = \mathfrak{T}_T$  and

$$\alpha_0 = \tau_0 = \{\eta i : 0 \leq i < v\} \cup \{T\} \quad (5.133)$$

where  $v = \lceil T/\eta \rceil$ .

Let  $\varepsilon = \varepsilon_0/9$ . Define for convenience  $s_i = \eta i$  (that are equispaced for  $i < v$ ) while  $s_v = T$ . Consider any  $\tau \geq \tau_0$ ; let  $\mathfrak{X}^\tau$  be a process; by equation (5.131)

$$\mathbb{P}\{\omega(\mathfrak{X}^\tau, \eta) \geq 9\varepsilon\} \leq \sum_{i=0}^{v-1} \mathbb{P}\left\{\sup_{s_i \leq t < s_{i+1}} \|\mathfrak{X}_t^\tau - \mathfrak{X}_{s_i}^\tau\|_H \geq 3\varepsilon\right\} \quad (5.134)$$

For the terms in the sum in equation (5.134) we use our version (equation (5.121)) of Etemadi's estimate to obtain

$$\mathbb{P}\{\omega(\mathfrak{X}^\tau, \eta) \geq 9\varepsilon\} \leq \sum_{i=0}^{v-1} \mathbb{P}\left\{\sup_{s_i \leq t < s_{i+1}} \|\mathfrak{X}_t^\tau - \mathfrak{X}_{s_i}^\tau\|_H > 3\varepsilon\right\} \leq v \frac{c_{10}}{\varepsilon^4} g(\eta) < \varepsilon_1 \quad (5.135)$$

by equation (5.132). So we have satisfied the second hypothesis of Theorem 4.5, in the form expressed in eqn. (4.9).

This concludes the proof of Theorem 5.14.

## 6. RESULTS ON MANIFOLDS

**6.1. Hypotheses for manifolds.** We again define, for  $v \in K(H)$ ,  $\|v\|_K \stackrel{\text{def}}{=} \|K^{-1}v\|_H$  as in Definition 5.10; similarly for scalar products. The following Theorem uses the following hypotheses on the manifold  $M$  and its embedding in  $H$ . Let  $\exp_x v$  be the exponential mapping of  $M$ . For convenience we denote by  $P_x : H \rightarrow T_x M$  the orthogonal projection  $P_x = \pi_{T_x M}$ .

**Hypotheses 6.1.** We assume what follows.

- (1) The manifold  $M$  is isometrically embedded in the Hilbert space  $H$  and it is a closed subset of it.

- (2) The second fundamental form of the embedding of the manifold  $M$  is uniformly bounded.

We suppose that there exists a compact operator  $K$  satisfying the requisites in the previous section 5.1, and constants  $c_e, c_p > 0$ , such that:

$$(3) \quad \mathbb{P}\{\mathfrak{X}_0 \in M\} = 1 \quad (6.2)$$

and

$$\mathbb{E}[\|\mathfrak{X}_0\|_K^4] < \infty \quad (6.3)$$

- (4) If  $x \in M \cap K(H)$  and  $v \in K(H)$  then  $P_x v \in K(H)$

- (5) and

$$\|P_x v\|_K \leq c_p (\|v\|_K + \|x\|_K \|v\|_H) \quad ; \quad (6.4)$$

- (6) if  $x \in M \cap K(H)$  and  $v \in T_x M \cap K(H)$  then  $\exp_x v \in M \cap K(H)$

- (7) and

$$\|(\exp_x v) - (v + x)\|_K \leq c_e \left( \|x\|_K \|v\|_H^2 + \|v\|_K \|v\|_H \right) e^{c_3 \|v\|_H} \quad (6.5)$$

The second hypothesis can be reformulated as follows.

**Proposition 6.6.** *The following are equivalent:*

- (1) *The second fundamental form of the embedding of manifold  $M$  is uniformly bounded.*  
 (2)  $\exists c_e > 0$  such that  $\forall x \in M, \forall v \in T_x M$ ,

$$\|v\|_H \leq 1/c_e \Rightarrow \|(\exp_x v) - (v + x)\|_H \leq c_e \|v\|_H^2 \quad (6.7)$$

## 6.2. Tightness of Interpolated Geodesic Processes.

**Theorem 6.8.** *Consider the interpolated geodesic processes  $\mathfrak{X}^\tau$  defined as in Section 3.5.1; restrict each  $\mathfrak{X}_t^\tau$  to  $t \in I = [0, T]$ . Under Hypotheses 6.1, these  $\mathfrak{X}^\tau$ , for  $\tau \in \mathfrak{T}_T$ , are a tight family in  $C(I; M)$ .*

Since this Theorem is proved using Theorem 5.14, then all corollaries of the latter hold also for the former. We have moreover this result.

**Corollary 6.9.** *Any limit point  $\mathfrak{X}$  of  $\mathfrak{X}^\tau$  is a process taking values in  $C(I; M)$  a.s.*

*Proof.* Since  $M \subset H$  was assumed to be closed, then  $C(I; M)$  is a closed subset of  $C(I; H)$ ; by construction  $\mathfrak{X}_t^\tau \in M$  for all  $t \in I$ , hence

$$\mathbb{P}(\mathfrak{X}^\tau \in C(I; M)) = 1 \quad (6.10)$$

so by Alexandrov's Theorem <sup>11</sup>

$$\mathbb{P}(\mathfrak{X} \in C(I; M)) = 1 \quad (6.11)$$

□

*Remark 6.12.* Nothing is specifically “infinite dimensional” in this approach: this theorem can be applied to finite dimensional manifolds as well. Recall that, by Nash embedding theorems, any finite dimensional Riemannian manifold can be isometrically embedded in  $H = \mathbb{R}^N$ ; and in this case we set  $K$  to be the identity; moreover equation (6.4) is trivially true. We then require that

$$\mathbb{P}\{\mathfrak{X}_0 \in M\} = 1 \quad , \quad \mathbb{E}[\|\mathfrak{X}_0\|_K^4] < \infty \quad ; \quad (6.13)$$

<sup>11</sup>In the version in Theorem 3.8.2 in [Bogachev, 1998], or Theorem 3.5 in [Vakhania et al., 2012]; see Theorem 6.11 in [Mennucci] for convenience.

then we require the bound on the second fundamental form, that implies equation (6.7) that in turn implies equation (6.5) (see Remark 5.86): under this conditions Theorem 6.8 holds.

*Proof of Theorem 6.8.* As in eqn. (3.42) in Section 3.5.1 we define

$$D(x, y, t, s) \stackrel{\text{def}}{=} \exp_x(\sqrt{s}P_x y) - x \quad (6.14)$$

and we define

$$L(x, t)v = P_x v \quad (6.15)$$

In this way, the random walk on the manifold can be seen as a special case of a random walk in  $H$ . We recall item 6 of Theorem 5.14:

$$\|D(x, v, t, s)\|_H \leq c_d \sqrt{s} \|v\|_H, \quad (6.16)$$

$$\sqrt{s} \|v\| \leq 1/c_d \Rightarrow \|D(x, v, t, s) - \sqrt{s}L(x, t)v\|_H \leq c_d s \|v\|_H^2. \quad (6.17)$$

The first one, when  $c_d \geq 1$ , is true for any embedded manifold, since the length of a curve is larger (or equal) than the distance between its end points, and  $\|P_x v\|_H \leq \|v\|_H$ . For the second one, for  $\sqrt{s} \|v\| \leq 1/c_e$  we write

$$\begin{aligned} \|D(x, v, t, s) - \sqrt{s}L(x, t)v\|_H &= \|\exp_x(\sqrt{s}P_x v) - (\sqrt{s}P_x v + x)\|_H \\ &\leq c_e s \|P_x v\|_H^2 \leq c_e s \|v\|_H^2 \end{aligned}$$

using equation (6.7) from Proposition 6.6.

To obtain item 5 of Theorem 5.14: substitute in equation (6.5) to obtain

$$\|(\exp_x P_x v) - (P_x v + x)\|_K \leq c_e \left( \|x\|_K \|P_x v\|_H^2 + \|P_x v\|_K \|P_x v\|_H \right) e^{c_3 \|P_x v\|_H}. \quad (6.19)$$

then we use  $\|P_x v\|_H \leq \|v\|_H$  again, and we use equation (6.4) so

$$\begin{aligned} &\|\exp_x(P_x v) - (P_x v + x)\|_K \leq \\ &c_e \|x\|_K \|v\|_H^2 e^{c_3 \|v\|_H} + c_e c_p (\|v\|_K + \|x\|_K \|v\|_H) \|v\|_H e^{c_3 \|v\|_H} = \\ &(c_e(1 + c_p) \|x\|_K \|v\|_H^2 + c_e c_p \|v\|_K \|v\|_H) e^{c_3 \|v\|_H} \end{aligned} \quad (6.20)$$

then replacing  $\sqrt{s}v$  for  $v$  this last satisfies equation (5.20) with  $c = c_e(1 + c_p)$ . So Theorem 6.8 can be straightforwardly seen as a corollary of Theorem 5.14.  $\square$

## 7. RESULTS ON STIEFEL MANIFOLDS

let  $V$  be a separable Hilbert space with  $\dim(V) \geq 2p$  (possibly infinite dimensional). We define the Hilbert space  $V^p$  and the Stiefel manifold  $\mathbf{St}(p, V)$  as in Section 2.2.

In the following two sections we will show that the above hypotheses 6.1 are satisfied when  $M = \mathbf{St}(p, V)$  is the Stiefel manifold: so the family of random walks is tight.

We will use these definitions with  $E = H$  or  $E = H^2$ .

**Definition 7.1.** If  $E$  is a vector space with a scalar product, we agree that, for  $x, v \in E^p$ ,  $A = x^\top v$  is the  $p \times p$  matrix defined by

$$A_{i,j} = \langle x_i, v_j \rangle_E. \quad (7.2)$$

We also agree that, given  $x \in E^p$  and  $A \in \mathbb{R}^{p \times p}$  the right product

$$y = xA \quad (7.3)$$

is the vector  $y \in E^p$

$$y_i = \sum_{j=1}^p x_j A_{j,i} \quad . \quad (7.4)$$

**7.1. Probabilities on Stiefel Manifolds.** When  $M = \text{St}(p, V)$  is a Stiefel manifold, it will be convenient to build the probabilistic infrastructure in Sec. 3.2 in this specific way.

Suppose that  $\tilde{\gamma} = N(0, \tilde{Q})$  is a centered non-degenerate Gaussian measure in the separable Hilbert space  $V$ . We will then define the operator  $Q : H \rightarrow H$  by tensor product

$$\langle x, Qy \rangle_H = \sum_{i=1}^p \langle x_i, \tilde{Q}y_i \rangle_V \quad (7.5)$$

so  $\gamma = N(0, Q)$  is a centered non-degenerate Gaussian measure in the separable Hilbert space  $H$ , given by the measure product

$$\gamma = \tilde{\gamma} \otimes \dots \otimes \tilde{\gamma} \quad (7.6)$$

Equivalently, if we consider  $x \in H$  as a r.v. with distribution  $\gamma$ , then the columns of  $x \in H$  will be independent r.v. each with distribution  $\tilde{\gamma}$ .

**Proposition 7.7.** *Given  $A \in O(p)$ , the action*

$$A : H \rightarrow H \quad , \quad x \mapsto xA \quad (7.8)$$

*maps identically*

$$\gamma = A_{\#} \gamma \quad (7.9)$$

*the probability  $\gamma$  to itself.*

**7.2. Tightness operator.** As noted in Remark 5.8, in the space  $V$  starting from  $\tilde{Q}$  we can define a compact operator  $\tilde{K} : V \rightarrow V$  such that  $\tilde{K}^{-1} \tilde{Q} \tilde{K}^{-1}$  is still trace class. We eventually define  $K : H \rightarrow H$  as

$$y = Kx \quad \text{when} \quad y_i = \tilde{K}x_i \quad (7.10)$$

So  $K$  commutes with the right multiplication by matrixes

$$(Kx)A = K(xA) \quad (7.11)$$

defined in Definition 7.1.

### 7.3. Tightness in Stiefel Manifolds.

**Theorem 7.12.** *Suppose that  $Y_t \sim N(0, Q)$  as defined in previous Section 7.1. Consider interpolated geodesic processes  $\mathfrak{X}^\tau$  defined as in Section 3.5.1 when  $M$  is a Stiefel manifold, having*

$$\mathbb{P}\{\mathfrak{X}_0 \in M\} = 1 \quad , \quad \mathbb{E}[\|\mathfrak{X}_0\|_K^4] < \infty \quad (7.13)$$

*and restrict each  $\mathfrak{X}_t^\tau$  to  $t \in I = [0, T]$ : these  $\mathfrak{X}^\tau$ , for  $\tau \in \mathfrak{T}_T$ , are a tight family in  $C(I; M)$ .*

In the following sections we will indeed show that all Hypotheses 6.1 are satisfied in Stiefel manifolds.

Since this Theorem is proved using Theorem 5.14, and this latter using Theorem 6.8, then all corollaries of Theorems 6.8 and Theorem 5.14 will hold also for Theorem 7.12.

We have moreover this result.

**Corollary 7.14.** *If the law of the starting r.v.  $\mathfrak{X}_0 = \mathfrak{X}_0^\top$  of the processes is invariant for right actions of  $A \in O(p)$ , then the law of  $\mathfrak{X}^\tau$  is invariant for right actions of  $A \in O(p)$ ; so this is true for any limit point  $\mathfrak{X}$  of  $\mathfrak{X}^\tau$ . So the above can be interpreted as a result for Grassmann manifolds as well.*

7.3.1. *More on geodesics.* The results from [Edelman et al., 1998] still hold, with minor adjustments in notation.

**Lemma 7.15.** *Given  $x \in M = \mathbf{St}(p, V)$  and  $v \in H$ , we have that  $v \in T_x M$  iff  $x^\top v$  is an asymmetric matrix.*

*Given  $x \in M = \mathbf{St}(p, V)$  and  $A \in O(p)$  orthogonal matrix, then  $xA \in M$ . The action  $x \mapsto xA$  is an isometry in  $H$  and hence in  $M$ .*

**Proposition 7.16** (Critical geodesics in  $\mathbf{St}(p, V)$ ). *Let  $\mathbf{St}(p, V)$  be endowed with the induced metric from  $H = V^p$ . Let  $\gamma : [0, 1] \rightarrow \mathbf{St}(p, V)$  be a path. Then the geodesic equation is  $\ddot{\gamma} + \gamma(\dot{\gamma}^\top \dot{\gamma}) = 0$ . Solutions to the geodesic equation exist for all time and are given by*

$$(\gamma(t)e^{At}, \dot{\gamma}(t)e^{At}) = (\gamma(0), \dot{\gamma}(0)) \exp t \begin{pmatrix} A & -S \\ \mathbb{I} & A \end{pmatrix} \quad (7.17)$$

where  $\mathbb{I}$  is the  $p \times p$  identity matrix and  $A = \gamma(0)^\top \dot{\gamma}(0)$ ,  $S = \dot{\gamma}(0)^\top \dot{\gamma}(0)$ .

Note that  $A$  is asymmetric and  $S$  is symmetric; moreover  $A = \gamma(t)^\top \dot{\gamma}(t)$ ,  $S = \dot{\gamma}(t)^\top \dot{\gamma}(t)$  are constant along the geodesic; and  $e^{At} \in O(p)$ .

Further properties of infinite dimensional Stiefel and Grassmann manifolds are discussed in [Harms and Mennucci, 2012]. In particular it is proven that any two points in those manifolds are connected by a minimal length geodesic.

We will now add more analysis to achieve the desired results.

*Remark 7.18.* Let  $\lambda \in \mathbb{R}, \lambda \neq 0$ , fix  $x \in M, v \in T_x M$  and set  $(\gamma(0), \dot{\gamma}(0)) = (x, v)$ . Define  $A = x^\top v$ ,  $S = v^\top v$  as above. In the geodesic equation (7.17), we multiply as follows

$$(\gamma(t)e^{At}, \lambda \dot{\gamma}(t)e^{At}) = (x, \lambda v) \begin{pmatrix} \mathbb{I} & 0 \\ 0 & \lambda^{-1} \mathbb{I} \end{pmatrix} \exp \left( t \begin{pmatrix} A & -S \\ \mathbb{I} & A \end{pmatrix} \right) \begin{pmatrix} \mathbb{I} & 0 \\ 0 & \lambda \mathbb{I} \end{pmatrix} \quad (7.19)$$

so

$$\begin{aligned} (\gamma(t)e^{At}, \lambda \dot{\gamma}(t)e^{At}) &= (x, \lambda v) \exp t \begin{pmatrix} A & -\lambda S \\ \lambda^{-1} \mathbb{I} & A \end{pmatrix} = \\ &= (x, \lambda v) \exp t \lambda^{-1} \begin{pmatrix} \lambda A & -\lambda^2 S \\ \mathbb{I} & \lambda A \end{pmatrix} \end{aligned} \quad (7.20)$$

We can use this relation as follows. Let now  $\theta = \|v\|$ ,  $\hat{v} = v/\theta$ ,  $\hat{A} = x^\top \hat{v}$ ,  $\hat{S} = \hat{v}^\top \hat{v}$  then setting  $\lambda = 1/\theta$

$$(\gamma(t)e^{t\theta \hat{A}}, \theta^{-1} \dot{\gamma}(t)e^{t\theta \hat{A}}) = (x, \hat{v}) \exp t\theta \begin{pmatrix} \hat{A} & -\hat{S} \\ \mathbb{I} & \hat{A} \end{pmatrix} \quad (7.21)$$

this formula decouples  $v$  into the *initial direction*  $\hat{v}$  and the *initial speed*  $\theta$ .

7.3.2. *Estimates.* Define  $\|v\|_K$  as in 5.10.

**Lemma 7.22.** *Recall the Definitions 7.1. For  $W \in \mathbb{R}^{k \times k}$  we use the norm*

$$|W| = \sqrt{\sum_{i,j=1}^k |W_{i,j}|^2} \quad (7.23)$$

and remark that

$$|WV| \leq |V| |W| \quad ; \quad (7.24)$$

we will use it with  $k = p$  or  $k = 2p$ ; if  $E$  is a vector space with a scalar product, then for  $v, w \in E$  we have

$$|v^\top w| \leq \|v\|_E \|w\|_E \quad (7.25)$$

and for  $v \in E^k$

$$\|vW\|_{E^k} \leq \|v\|_{E^k} |W| \quad (7.26)$$

by Cauchy-Schwarz inequality.

**Lemma 7.27.** *Consider the orthogonal projection  $\pi_T : H \rightarrow H$  to a hyperplane*

$$T = \{x \in H : \forall i = 1, \dots, h, \langle w_i, x \rangle_H = 0\} \quad (7.28)$$

orthogonal to  $w_1, \dots, w_h \in H$ , where those vectors are orthogonal but not orthonormal: then

$$\pi_T v = v - \sum_{i=1}^h w_i \frac{\langle w_i, v \rangle_H}{\|w_i\|_H^2} \quad . \quad (7.29)$$

We immediately note that if  $v, w_i$  are in a vector subspace  $E$  of  $H$ , then  $\pi_T v$  will be in the same  $E$ . Starting from equation (7.29) we estimate

$$\|\pi_T v\|_K \leq \|v\|_K + \sum_{i=1}^h \|w_i\|_K \frac{\|v\|_H}{\|w_i\|_H} \quad . \quad (7.30)$$

The tangent plane  $T = T_x M$  to the Stiefel manifold is such a plane, with

•

$$w_i = (0, \dots, 0, x_i, 0, \dots, 0) \quad (7.31)$$

containing the  $i$ -th column of  $x$  in position  $i$ -th; this for  $i = 1, \dots, p$ ;

• and then for  $i = p+1, \dots, p(p+1)/2$

$$w_i = (0, \dots, 0, x_h, 0, \dots, 0, -x_k, 0, \dots, 0) \quad (7.32)$$

containing the  $h$ -th column of  $x$  in position  $k$ -th and vice versa, and with a minus sign;

so by the diagonal structure (7.10) of  $K$  and by (7.29) above we obtain this: if  $x \in M \cap K(H)$  and  $v \in K(H)$  then  $\pi_{T_x M} v \in K(H)$ .

Moreover such  $w_i$  are mutually orthogonal; and  $\|w_i\|_H = 1$  for  $i = 1, \dots, p$ , while  $\|w_i\|_H = 2$  otherwise; while  $\|w_i\|_K \leq \|x\|_K$  in all cases; so in conclusion

$$\|\pi_{T_x M} v\| \leq c_p (\|v\|_K + \|x\|_K \|v\|_H) \quad (7.33)$$

for a  $c_p > 0$  independent of  $x, v$ . This proves estimate eqn. (6.4) in Hypotheses 6.1.

The above suggests that equation (6.4) in Hypotheses 6.1 may hold for other manifolds, as long as the embedding in  $H$  has finite codimension.

**Lemma 7.34.** *Let  $\tilde{K} : V \rightarrow V$  a linear continuous injective operator. Recall that  $H = V^p$  and we defined  $K : H \rightarrow H$  in eqn. (7.10) as*

$$y = Kx \quad \text{when} \quad y_i = \tilde{K}x_i \quad . \quad (7.35)$$

*So  $K$  is a linear continuous operator and commutes with the right multiplication by matrixes*

$$(Kx)A = K(xA) \quad . \quad (7.36)$$

*There is a constant  $c > 0$  such that, for all  $x \in M \cap K(H), v \in T_x M \cap K(H)$  and the geodesic with*

$$(\gamma(0), \dot{\gamma}(0)) = (x, v) \quad , \quad (7.37)$$

*we have*

$$(\|\gamma(1) - x - v\|_K + \|\dot{\gamma}(1) - v + Sx\|_K) \leq c \left( \|x\|_K \|v\|_H^2 + \|v\|_K \|v\|_H \right) e^{c\|v\|_H} \quad . \quad (7.38)$$

*Note that  $c$  does not depend on  $K$  but only on  $p$ .*

*This proves equation (6.5) in Hypotheses 6.1.*

*Proof.* Fix  $x \in M, v \in T_x M$  and set  $\theta = \|v\|, \hat{v} = v/\theta$ . We will use the formula seen in eqn. (7.21) with  $t = 1$ . We define

$$\begin{aligned} \hat{A} &= x^\top \hat{v} \quad , \quad \hat{S} = \hat{v}^\top \hat{v} \quad , \\ Z &= \begin{pmatrix} \hat{A} & -\hat{S} \\ \mathbb{I} & \hat{A} \end{pmatrix} \quad , \quad B = \begin{pmatrix} -\hat{A} & 0 \\ 0 & -\hat{A} \end{pmatrix} \quad , \quad \Theta = \begin{pmatrix} \mathbb{I} & 0 \\ 0 & \theta \mathbb{I} \end{pmatrix} \end{aligned} \quad (7.39)$$

so the formula (7.21) becomes

$$(\gamma(t), \dot{\gamma}(t)) = (x, \hat{v}) \exp(t\theta Z) \exp(t\theta B) \Theta \quad (7.40)$$

then

$$\begin{aligned} (\gamma(t), \dot{\gamma}(t)) &= (x, \hat{v}) \left( \sum_{i \geq 0, j \geq 0} (t\theta)^{i+j} \frac{Z^i}{i!} \frac{B^j}{j!} \right) \Theta = \\ &= (x, \hat{v}) \left( \mathbb{I} + t\theta(Z + B) + \sum_{i, j, i+j \geq 2} (t\theta)^{i+j} \frac{Z^i}{i!} \frac{B^j}{j!} \right) \Theta = \\ &= (x + tv, v - t\theta^2 xS) + (x, \hat{v}) \left( \sum_{i, j, i+j \geq 2} (t\theta)^{i+j} \frac{Z^i}{i!} \frac{B^j}{j!} \right) \Theta \end{aligned} \quad (7.41)$$

Now

$$|\hat{A}| \leq p \quad , \quad |\hat{S}| \leq 1 \quad , \quad |\hat{B}| \leq 2p \quad , \quad |Z| \leq \sqrt{3p+1} \quad (7.42)$$

and setting  $t = 1$

$$\begin{aligned} & \sqrt{\|\gamma(1) - x - v\|_K^2 + \|\dot{\gamma}(1) - v + \theta^2 x \hat{S}\|_K^2} \leq \\ & \sqrt{\|x\|_K^2 + \|\hat{v}\|_K^2} \left| \sum_{i,j,i+j \geq 2} \theta^{i+j} \frac{Z^i}{i!} \frac{B^j}{j!} \right| |\Theta| \leq \\ & \sqrt{\|x\|_K^2 + \|\hat{v}\|_K^2} \sum_{i,j,i+j \geq 2} |\theta|^{i+j} \frac{|Z|^i}{i!} \frac{|B|^j}{j!} \sqrt{(1 + p\theta^2)} \leq \\ & \sqrt{\|x\|_K^2 + \|\hat{v}\|_K^2} \theta^2 g(\theta) \end{aligned}$$

where we are using the fact (7.11) that left multiplication by  $K$  and right multiplication by a matrix are associative; and

$$\begin{aligned} g(s) &= \sum_{i,j,i+j \geq 2} s^{i+j-2} \frac{(3p+1)^{i/2}}{i!} \frac{(2p)^j}{j!} = \\ & \sum_{2 \leq n} \sum_{0 \leq k \leq n} \frac{s^{n-2}}{n!} \left( \binom{n}{k} (3p+1)^{k/2} \binom{n}{n-k} (2p)^{n-k} \right) = \\ & \sum_{2 \leq n} \frac{s^{n-2}}{n!} \left( \sqrt{3p+1} + 2p \right)^n = \\ & = \frac{1}{s^2} (\exp a - 1 - a) \quad \text{with} \quad a = s \left( \sqrt{3p+1} + 2p \right) . \quad \square \end{aligned}$$

The first and second assumptions in Hypotheses 6.1 are obviously true for Stiefel manifolds: indeed the curvatures and second fundamental form are uniformly bounded, since Stiefel manifolds are homogeneous spaces. Nonetheless we can provide this estimate that satisfies (6.7).

**Corollary 7.45.** *There is a constant  $c > 0$  such that for all  $x \in M, v \in T_x M$  and the geodesic with*

$$(\gamma(0), \dot{\gamma}(0)) = (x, v) \quad (7.46)$$

we have

$$\|\gamma(1) - x - v\|_H \leq c \min\{\|v\|_H, \|v\|_H^2\} . \quad (7.47)$$

*Proof.* We note that the Stiefel manifold  $\mathbf{St}(p, V)$  has diameter  $d$ , so that for  $v \geq d$  we can estimate

$$\|\gamma(1) - x - v\|_H \leq d + \|v\|_H \quad (7.48)$$

while for  $v \leq d$  we use the above lemma 7.34 with  $K$  being the identity, recalling that  $\|x\|_K = \sqrt{p}$  in this case.  $\square$

## 8. CONCLUSIONS AND FUTURE DEVELOPMENTS

We now know that, under appropriate hypotheses, the processes  $\mathfrak{X}^\tau$  have narrow limit points  $\mathfrak{X}$  when the partition  $\tau$  becomes finer and finer; these  $\mathfrak{X}$  are random functions in  $C(\mathbb{R}^+; S)$  with  $S = H$  or  $S = M$  an embedded manifold.

There are multiple questions left unanswered, material for future research.

- Do the limit points enjoy some standard property? It seems plausible that they may enjoy some kind of *Markov Property*, for example.

- Under which additional hypotheses can we say that there is an unique limit point?
- Can we then characterize the limit points as solutions to a kind of SDE?  
(These two questions are in synergy).
- Can we expand the results to more general cases of random walks, for example, where the constants in the hypothesis are not “uniform” but rather they may grow (*e.g.* be bounded by a function of the distance from a given point)?
- Consequently, are there other infinite dimensional manifolds where the present results hold true?

All the above questions are starting point for future research.

#### APPENDIX A. USEFUL LEMMAS

In this section we have collected the technical Lemmas used here and there in the paper.

**Lemma A.1.** *For  $E$  space with scalar product and  $v, w \in E$ ,*

$$|v + w|^2 \leq 2|v|^2 + 2|w|^2 \quad . \quad (\text{A.2})$$

*Proof.*

$$|v + w|^2 \leq (|v| + |w|)^2 \leq 2|v|^2 + 2|w|^2 \quad (\text{A.3})$$

□

In the following *monotonic* means *monotonically weakly increasing* that is  $s \leq t \Rightarrow g(s) \leq g(t)$ .

**Lemma A.4.** *Let  $\beta \in \mathbb{R}$ . Let*

$$t_0 = 0 < t_1 < t_2 < \dots \quad (\text{A.5})$$

*and let  $\delta_n = t_{n+1} - t_n$ . Suppose  $b_n$  is a real valued sequence with  $b_n \geq \beta$  for all  $n$ . Suppose that*

$$\varphi = \varphi(t, x) : [0, \infty) \times [\beta, \infty) \rightarrow [0, \infty) \quad (\text{A.6})$$

*is a continuous non negative function, such that  $\varphi(\cdot, x)$  and  $\varphi(t, \cdot)$  are monotonically increasing. Let  $f : [0, \infty) \rightarrow [\beta, \infty]$  be a solution of*

$$\begin{cases} f'(t) = \varphi(t, f(t)) \\ f(0) = b_0 \end{cases} \quad (\text{A.7})$$

*(possibly  $f(t) = \infty$  for large  $t$ .) If*

$$b_{n+1} \leq b_n + \varphi(t_n, b_n)\delta_n \quad (\text{A.8})$$

*holds then*

$$b_n \leq f(t_n) \quad . \quad (\text{A.9})$$

*Proof.* Proof by induction. Note that  $f$  is monotonic since  $f' \geq 0$  but then it is convex since  $f'$  is monotonic.

$$\begin{aligned} b_{n+1} &\leq b_n + \varphi(t_n, b_n)\delta_n \leq f(t_n) + \varphi(t_n, f(t_n))\delta_n \\ &= f(t_n) + f'(t_n)\delta_n \leq f(t_{n+1}) \end{aligned} \quad (\text{A.10})$$

□

Note that indeed (A.8) can be rewritten as

$$\frac{b_{n+1} - b_n}{t_{n+1} - t_n} \leq \varphi(t_n, b_n) \quad . \quad (\text{A.11})$$

**Lemma A.12.** *Let*

$$t_0 = 0 < t_1 < t_2 < \dots \quad (\text{A.13})$$

*and let  $\delta_n = t_{n+1} - t_n$ ; fix  $c_7 > 0, c_8 > 0$ . Suppose  $b_n$  is a real valued sequence with  $b_0 = 0, b_n \geq 0$  that satisfies*

$$b_{n+1} \leq b_n + 2\delta_n(c_7\sqrt{b_n}\sqrt{t_n} + c_8t_n) \quad ; \quad (\text{A.14})$$

*then*

$$b_n \leq (c_7 + 2c_8)g(t_n) \quad \text{with} \quad g(t) = \frac{e^{c_7t} - 1 - c_7t}{c_7^2} \quad . \quad (\text{A.15})$$

*Moreover, set*

$$\hat{\varepsilon} = \frac{2}{c_7 + 2c_8} \quad , \quad (\text{A.16})$$

*then*

$$\forall n, \quad t_n \leq \hat{\varepsilon} \Rightarrow b_n \leq t_n^2(c_7 + c_8) \quad (\text{A.17})$$

*and note that  $b_0 = b_1 = 0$ .*

*Proof.* Consider a solution of the ODE

$$\begin{cases} f'(t) = 2c_7\sqrt{f(t)}\sqrt{t} + 2c_8t \\ f(0) = 0 \end{cases} \quad ; \quad (\text{A.18})$$

(that is (A.7) for this special case). Since

$$\sqrt{ab} \leq \frac{a+b}{2} \quad (\text{A.19})$$

then

$$f'(t) \leq c_7f(t) + (c_7 + 2c_8)t \quad (\text{A.20})$$

substituting  $f(t) = g(t)e^{c_7t}$  and with some calculations we obtain

$$f(t) \leq (c_7 + 2c_8)g(t) \quad \text{with} \quad g(t) = \frac{e^{c_7t} - 1 - c_7t}{c_7^2} \quad . \quad (\text{A.21})$$

Since

$$f'(t) \geq 2c_8t \quad (\text{A.22})$$

then

$$f(t) \geq c_8t^2 \quad (\text{A.23})$$

in particular for any solution we have  $f(t) > 0$  and  $f'(t) > 0$  for  $t > 0$ . We have  $f'(0) = 0$  so  $f(t) \leq t$  for  $t \leq \varepsilon$  with  $\varepsilon$  small; more precisely, note that  $g(t)$  is convex and increasing and  $g(0) = g'(0) = 0$  so we set  $\varepsilon$  to be the unique positive solution of

$$(c_7 + 2c_8)g(t) = t \quad ; \quad (\text{A.24})$$

moreover  $g(t) \geq t^2/2$  so we know that

$$\varepsilon \geq \frac{2}{c_7 + 2c_8} \quad . \quad (\text{A.25})$$

Now we set

$$\hat{s} = \sup\{s \geq 0 : t \leq s \Rightarrow f(t) \leq t\} \quad (\text{A.26})$$

note that  $\varepsilon \leq \hat{s} \leq 1/c_8$ ; for  $t \in [0, \hat{s}]$

$$f'(t) \leq 2(c_7 + c_8)t \quad (\text{A.27})$$

so

$$f(t) \leq (c_7 + c_8)t^2 \quad . \quad (\text{A.28})$$

□

**Lemma A.29.** *Let*

$$t_0 = 0 < t_1 < t_2 < \dots \quad (\text{A.30})$$

and let  $\delta_n = t_{n+1} - t_n$ . Suppose  $b_n$  is a real valued sequence. If, for  $c_7 > 0, c_8 \geq 0, c_9 \geq 0$ ,

$$b_{n+1} \leq b_n(1 + c_7\delta_n) + \delta_n(c_8 + c_9t_n) \quad (\text{A.31})$$

holds then

$$\begin{aligned} b_n &\leq b_0 e^{c_7 t_n} + (e^{c_7 t_n} - 1)(c_8/c_7 + c_9/c_7^2) - c_9 t_n/c_7 = \\ &e^{c_7 t_n} \left( b_0 + c_8/c_7 + c_9/c_7^2 \right) - \left( (c_8 + c_9 t_n)/c_7 + c_9/c_7^2 \right) \quad . \end{aligned} \quad (\text{A.32})$$

*Proof.* Indeed (A.31) can be rewritten as

$$\frac{b_{n+1} - b_n}{t_{n+1} - t_n} \leq c_7 b_n + c_8 + c_9 t_n \quad (\text{A.33})$$

and the associated differential equation is

$$f'(t) = c_7 f(t) + c_8 + c_9 t \quad (\text{A.34})$$

that has solution

$$f(t) = e^{c_7 t} f(0) + (e^{c_7 t} - 1)(c_8/c_7 + c_9/c_7^2) - c_9 t/c_7 \quad (\text{A.35})$$

so this proves the result. □

## APPENDIX B. PROOFS

*Proof of Proposition 3.15.* If  $c = 0$  then

$$\mathbb{E}[g(\delta\|Y\|)] = \delta^\alpha \mathbb{E}[\|Y\|^\alpha] \quad (\text{B.1})$$

so we set

$$\tilde{c} = \mathbb{E}[\|Y\|^\alpha] \quad . \quad (\text{B.2})$$

Otherwise we set

$$\tilde{c} = \mathbb{E} \left[ \|Y\|^\alpha e^{c c_t \|Y\|} \right] \quad , \quad (\text{B.3})$$

so

$$\mathbb{E}[g(\delta\|Y\|)] = \delta^\alpha \mathbb{E} \left[ \|Y\|^\alpha e^{c \delta \|Y\|} \right] \leq \delta^\alpha \mathbb{E} \left[ \|Y\|^\alpha e^{c c_t \|Y\|} \right] = \tilde{c} \delta^\alpha \quad (\text{B.4})$$

□

We recall Proposition 1.13 from [Da Prato, 2006].

**Proposition B.5.** *Let  $Y = N(a, Q)$  and*

$$\lambda_1 = \max_{\|x\| \leq 1} \langle x, Qx \rangle_H \quad (\text{B.6})$$

be the highest eigenvalue of  $Q$ . Then for  $0 < \varepsilon < 1/\lambda_1$

$$\int_H e^{\varepsilon \|x\|^2/2} d\gamma(x) = \frac{\exp \left( -\frac{1}{2} \langle a, (1 - \varepsilon Q)^{-1} a \rangle_H \right)}{\sqrt{\det(1 - \varepsilon Q)}} \quad (\text{B.7})$$

whereas for  $\varepsilon \geq 1/\lambda_1$  the integral is infinite.

*Proof of Proposition 3.21.* Set  $c_t = 1$  for simplicity. By the previous proposition, for any  $\lambda > 0$ ,

$$\mathbb{E}[e^{\lambda \|Y\|_H}] < \infty . \quad (\text{B.8})$$

For  $k \in \mathbb{N}$  and  $a > 0$  we have  $a^k s^k \leq k! e^{as}$  hence choosing  $k = \lceil \alpha \rceil$ ,

$$s^\alpha e^{sc} \leq \frac{k!}{a^k} e^{s(a+c)} \quad (\text{B.9})$$

so again we define

$$\tilde{c} = \mathbb{E}[g(\|Y\|)] < \infty ; \quad (\text{B.10})$$

and we proceed as in the above proof of Proposition 3.15.  $\square$

*Proof of Proposition 3.39.* By contradiction, suppose there is; up to substituting  $f(n)$  with  $\bigcup_{j=0}^n f(j)$  we can suppose that  $f$  is monotonic. Let  $c_t = 1$  for simplicity. We build iteratively  $\tau \in \mathfrak{T}$  such that  $\forall n, \tau \not\subseteq f(n)$ , in this way. We will build a (non decreasing) sequence  $n_m \in \mathbb{N}$  such that  $n_m \rightarrow_m \infty$ , and a sequence  $t_0 = 0 < t_1 < \dots \in \tau$  satisfying the requisites in Definition 3.23. Let  $t_0 = 0, t_1 = 1, n_0 = n_1 = 0$ ; for  $m \geq 1$  having chosen  $t_m \in \tau$  and  $n_m$ , we look for  $k > n_m$  such that there is a  $t \in f(k) \setminus f(n_m) \wedge t \geq t_m + 1/2$ ;

- if there is no such  $k$ , we stop the iterative process by adding to  $\tau$  an arbitrary sequence  $t_{m+1} < t_{m+2} < \dots$  with  $t_{m+j} \notin \bigcup_k f(k)$  and  $1/2 < t_{m+j+1} - t_{m+j} < 1$ ; we set  $n_{m+j} = n_m + j$ ; all that for  $j \geq 0$ .
- If there is such  $k, t$ , we add to  $\tau$  an arbitrary sequence

$$t_{m+1} < t_{m+2} < \dots < t_{m+l} = t \quad (\text{B.11})$$

such that

$$1/2 < t_{m+j+1} - t_{m+j} < 1 \quad \text{for } j = 0, \dots, l-1 ; \quad (\text{B.12})$$

then we set  $n_{m+1} = \dots = n_{m+l} = k$ ; then we repeat the iteration using  $m+l$  as the new  $m$ .

In any case we obtain that for infinitely many  $m$  there is a  $l$  such that  $t_{m+l} \notin f(n_m)$ .  $\square$
